A 1975 survey by Calin and Fries of 2400 healthy individuals found that 20 percent of males with the B27 marker and 17 percent of the females "had definite and symptomatic ankylosing spondylitis. These figures are ten times the expected frequency in males and 80 times in females."

Since B27 occurs in approximately seven percent of the Caucasian population, this finding indicates that the disease is present in about one percent of that group.

B27 is also associated with Reiter's syndrome, a form of arthritis which can follow bacterial infections such as Shigella dysentary.

A 1977 follow-up study of Shigella victims by Calin and Fries found that 20 percent of B27 positive individuals developed Reiter's syndrome following infections with the Shigella bacterium.

"Whether the same 20 percent subset of the B27 population are at risk of developing ankylosing spondylitis following an unspecified environmental event remains unknown," say the authors. At present, the disease has no known link with infection.

Calin and Fries caution against using the presence of B27 as a marker for disease. "B27 detects a genetic marker and not a clinical syndrome," they say. "Four out of five patients who are B27 positive will not have ankylosing spondylitis nor will they ever develop it."

The search for causative agents and mechanisms continues and may reveal a complex relationship between several white blood cell antigens and environmental events, say the authors.

In the meantime, "the technology of the present can provide major benefits for the recognized patient with ankylosing spondylitis."

STANFORD—A dog suffering from a rare sleep disorder was reported missing Thursday, August 17, by the Sleep Research Center at Stanford University Medical Center.

The dog, an adult male Doberman pinscher, disappeared Wednesday night from a home in the vicinity of Castro St. and El Camino Real in Mountain View.

"We're very anxious to recover the dog," said Dr. William C. Dement, director of the center. "It is a crucial part of an on-going research project at Stanford to study this disease."

The dog suffers from narcolepsy, a disorder characterized by frequent attacks of complete paralysis. The disease, which is estimated to afflict 250,000 Americans, is not painful, but is disabling to humans, said Dement.

The black and tan colored dog has cropped ears and tail and is wearing a choke chain and flea collar but no tags.

Persons with information regarding the dog should call the Stanford Sleep Research Center (497-6601). A reward is offered for return of the dog, no questions asked.

STANFORD—Deficiencies in some of Stanford University Hospital's supplemental services noted during a recent survey by the state Department of Health reflect the need to upgrade facilities in accordance with state law, and will not affect patient care, according to hospital officials.

Under new state law Title 22, permits to operate the outpatient, coronary care, intensive care and newborn intensive care services had been temporarily withheld because of the need for a plan to correct space and organizational deficiencies found during the deparment's survey in April.

"Once the health department receives an acceptable plan of corrections of these deficiencies, it will approve the permits necessary for continued operation of the services," said Guy Seaton, health facilities evaluator at San Jose.

"I see no problem with licensing of the services,"said hospital administrator Gary Mecklenburg. "I view the report of the health department's April survey as a positive one. The department noted a positive response on the part of the hospital to previous recommendations it made in last year's survey."

Stanford has already announced plans to remodel its intensive care nursery, and has indicated to the health department that it will take action to fully comply with its requirements.

The health department survey was conducted in conjunction with the survey by the Joint Commission on Accreditation of Hospitals (JCAH). The JCAH, which received the recommendations of both the California Medical Association and the state health department, granted Stanford hospital full, two-year accreditation.

The department report of deficiencies "does not reflect a problem with the quality of patient care at Stanford," said Seaton, "but primarily was a matter of space requirements, and overcrowding in critical care areas."

The basic problem is one of providing up-to-date services in a physical plant which doesn't lend itself to expansion, he said. Stanford hospital was built 20 years ago.

Other hospitals in the area have encountered similar difficulties with space, said Seaton, and are planning their own building projects.

Under the new law, the coronary care, intensive care and newborn nursery services at Stanford hospital will require extensive remodeling.

Current law also requires that outpatient clinics either be licensed separately or as part of the hospital. Stanford clinics have been a part of the hospital.

In clinics which operate as part of a hospital, practicing physicians must be part of the medical staff that has hospital privileges.

At present, Mecklenburg explained, there is a small number of clinical faculty members who teach in the clinics on a voluntary basis but who are not members of the medical staff and do not admit patients.

A decision to license the clinics either separately or as part of the hospital will be made soon, he said.

Mecklenburg added that other citations, including those in dietetics and laundry services, and in medical records, are being corrected.

STANFORD—Legislation which would have clarified existing law governing billing of professional fees by salaried faculty physicians has been deferred at the request of Stanford and University of Southern California officials.

According to Robert E. Freelen, director of government relations, the reasons are timing and because Stanford and USC officials have concluded it is an important public policy issue that should be fully debated before a law is passed.

Freelen said that based on recommendation from Stanford and USC, Assemblyman Gordon Duffy (R-Hanford), sponsor of the proposed legislation, has agreed to conduct interim hearings in December.

"By handling it in this manner," Freelen said, "the State Assembly Health Committee will hear from all individuals and groups who have an interest in this matter before the bill is reintroduced in the next legislative session."

The legislation was an amendment to Assembly Bill 1551. It would have clarified the law under which faculty physicians who practice in clinics operated by private university medical schools charge for professional services rendered to patients.

Stanford clinics currently operate on this basis, but the legality of the practice is under investigation by the State Bureau of Medical Quality Assurance. The investigation was brought about by formal charges filed by the Union of American Physicians, and Dr. Eugene Dong, Jr., an associate professor of surgery.

They have alleged the faculty professional practice plan violates section 2008 of the California Business and professions Code which states that medical schools may employ salaried physicians and surgeons "if no charge for professional services rendered patients is made by such institution...."

However, Stanford maintains that its practice plan does not violate this section of the law since it is the faculty physicians, and not the institution, that determine when and how to treat the patients, and when and how much to charge the patients for the services rendered.

Furthermore, Stanford attorneys have pointed out that in cases which have dealt with this issue, the courts have never held that this section of the Business and Professions Code applies to faculty practice plans at medical schools.

Freelen said Stanford supports legislation that would remove any doubt which exists regarding the propriety of medical schools or their faculty physicians to charge fees for care they render patients.

"Direct clinical care to patients is an obvious and necessary part of teaching medical students, interns and residents," Freelen said. "In this process, faculty physicians provide services to patients. A system of charging for such services has been in existence in all of the medical schools of California and the nation in one form or another for years.

"No medical school in the country provides, or could provide, these services free of charge."

Freelen emphasized the proposed legislation is intended to clarify the issue, not to allow institutions to interfere with the manner in which faculty physicians conduct their clinical practice.

"It will not change the fact that faculty physicians are personally responsible for the professional services rendered patients," he said.

The change sought by Stanford and USC has been narrowly written to include only physicians on the faculties of university medical schools which operate clinics for the purposes of medical education, he said.

"The public policy of the State of California will not be changed by such an amendment," Freelen noted. "It would simply incorporate into the statutes the existing, long-standing manner in which faculty physicians of California's medical schools conduct their clinical practice with teaching patients."

STANFORD--The Stanford Heart Disease Prevention Program has been awarded a $6.5 million grant over the next five years to study the effect of comprehensive health education campaigns on the health of California communities.

The new study will be known as the Stanford Community Health Projects. Dr. John W. Farquhar, professor of medicine and director of the Heart Disease Prevention Program, is principal investigator.

Monterey County, as well as other cities and counties in the state, will participate in the projects.

The new study is based on experience gained from the recently concluded Stanford Three Community Study. According to that study, community-based health education which relies heavily on mass media can persuade people to change their life style and improve their health status.

In the new project, investigators from the School of Medicine, the Department of Communication and the School of Education will develop mass media education programs to be used in several cities with populations of 50-150,000.

In addition, both youth and adult group health education will be organized.

According to Farquhar, researchers will work with interested organizations within the cities so that the educational effort will be run to a considerable extent by the cities themselves.

The health of residents will be continuously monitored for cardiovascular risk: including blood pressure, relative weight, plasma lipoprotein levels and smoking, exercise and dietary habits.

In addition, a team from the Medical School will carry out surveillance studies for death and disability due to cardiovascular disease. Changes in community knowledge, attitudes and behavior related to health will also be recorded.

The former Three Community Study had shown that risk factors associated with heart disease could be significantly reduced in communities receiving comprehensive health education.

Focus of the new study, according to Dr. Peter Wood, co-principal investigator, is to determine for the first time the effect of such health education campaigns on actual heart attack and death rates in entire communities.

A clear decline in U.S. cardiovascular disease rates in recent years, says Farquhar, is attributed in part to healthful changes in lifestyle such as reduced tobacco consumption, improved dietary habits and increased exercise levels.

"This important new funding should enable us to refine, strengthen and pretest cost-effective mass media methods to accelerate this welcome national trend towards better health," says Farquhar.

Such education methods, he says, then will be available for wider use nationally.

The Stanford Heart Disease Prevention Program is now funded for various multidisciplinary research activities at a direct cost level of $2.1 million per year, making it one of the largest national research programs in the prevention of heart disease.

Dr. Nathan Maccoby, professor of communication, is co-principal investigator of the study. Other researchers include Janet Alexander of the Department of Communication; and Drs. Carl Thoresen and Thomas Coates of the School of Education.

The Medical School team includes Drs. Stewart Agras, Byron W. Brown, Jr., Stephen Fortmann, William Haskell, Stephen Hulley, Ralph Paffenbarger, and Barr Taylor.

STANFORD—A charge of unfair labor practices regarding an employee opinion survey held at Stanford Medical Center has been dismissed by an administrative law judge of the National Labor Relations Board (NLRB).

United Stanford Employees (USE) had filed the charge with NLRB a few days after the survey was underway in February 1977.

In April 1977, NLRB regional office in San Francisco found the charges without merit, and refused to issue a complaint.

USE appealed the decision to the NLRB's General Counsel in Washington, D.C. for hearing before an administrative law judge.

Judge Stanley Gilbert has now dismissed the complaint "in its entirety," finding all charges without merit.

Anne Schlagenhaft, then president of the union, had charged that the employee survey would bypass the union in dealing with employees the union represents, and that it would undermine the union's organizational efforts among unrepresented employees.

According to Ron Twomey, Medical Center director of personnel, the survey was not designed to interfere with union rights; elections would not be held for some time and no organizational activities were underway.

The judge confirmed that the surveys were not administered in a "preelection context" and did not violate the NLRB act.

Gilbert also noted that administering the surveys did not constitute "direct dealing" with employees represented by the union.

"There is nothing in the record as a whole that would warrant a finding that the surveys were calculated to interfere with, restrain or coerce employees in the exercise of their rights...".

Twomey said the survey was designed to examine major categories of employee opinions, including job satisfaction and supervisory practices.

The hospital, he says, "not only has a right, but also a responsibility to ask employees for their opinions in order to manage more effectively the Medical Center and its important patient care functions."

The judge pointed out actions taken as a result of the survey include upgrading the quality of food and expanding the seating capacity of the cafeteria, upgrading the Medical Center *Memo* publication, and providing more information about affirmative action.

Another primary result of the survey, says Twomey, was the improvement and expansion of the supervisory development program.

None of these actions violated the NLRB act, according to the judge.

STANFORD—Patients with chronic hepatitis B virus infections may participate in ongoing therapy trials at Stanford University Medical School, testing two antiviral drugs.

"Encouraging results suggest that a combination of these two drugs, interferon and vidarabine (adenine arabinoside), may be more effective in treating chronic hepatitis B infections than either drug alone," says Dr. Richard B. Pollard of the division of infectious diseases.

Interferon, a protein which inhibits viral growth, is normally produced by the body in response to viral infection. Vidarabine, known to inhibit replication of certain DNA viruses in tissue culture, has been used by the Stanford researchers in the treatment of two patients with hepatitis B infections.

Fourteen patients were recently treated with the two drugs in combination, with very encouraging results, says Pollard, but more studies are needed.

To date, there is no other treatment available for chronic hepatitis B infection.

Interested patients may contact the division of infectious diseases at (415) 497-5715.

STANFORD—Three of four causes of action in a $1.2 million damage suit filed against Stanford University Hospital have been dismissed by Santa Clara County Superior Court Judge Marilyn Pestarino Zecher.

No ruling was made, however, on a fourth cause of action involving a former employee, allowing further action on the matter by the court.

The suit had been filed earlier this year by Conroe C. McGee, a current employee, and former employee Frank P. Petta.

In addition to the hospital and 20 John Does, three persons were named as defendants, including former Facilities Department director Jim McNally, and chief engineer William Ferguson and general foreman David Dominguez.

The court's ruling dismisses all action against both Ferguson and Dominguez.

McGee and Petta had each sought $100,000 in general damages and $500,000 in punitive damages.

Judge Zecher dismissed McGee's claims. McGee, a hospital employee for 10 years, had alleged he was asked to accept a demotion by McNally earlier this year so Dominguez could be named general foreman. McGee refused, although Dominguez was later named to the post.

The court did not rule on Petta's charge that McNally gave him a poor performance rating, which he said prevented him from obtaining other employment after he left the hospital.

When the suit was filed last April, Stanford Hospital officials denied that the hospital had acted improperly in dealing with personnel actions taken concerning Petta and McGee.

STANFORD—Stanford University Hospital should continue to maintain a closed medical staff restricted to faculty physicians in the hospital-based clinical services, the board of directors has decided after six months of hearings and deliberations.

The board, however, endorsed the hospital's long-standing "open-staff" policy regarding physicians who admit patients to the medical and surgical services of the hospital, and said "it should be continued in the foreseeable future."

Hospital-based clinical services include anesthesia, cardiology, neurology and pathology laboratories, and the radiology service with its diagnostic, nuclear medicine, radiotherapy divisions and all other specialized laboratories.

Generally, these services have been operated under a closed staff restricted to medical school faculty. Some physicians, however, have maintained that these services should be opened to community specialists in these fields.

The hospital board, headed by Palo Alto attorney Conrad Gullixson, released its long-awaited decision Tuesday (Aug. 1.).

The decision calls for restricting future staff privileges in the hospital-based clinical services to the full-time and part-time paid faculty of the Stanford University School of Medicine.

The board granted some exceptions. They include community physicians who presently hold privileges in hospital-based clinical services, and community physicians who qualify under the city contract.

These exceptions, the board explained, are required to avoid undue personal hardship for community physicians presently on the medical staff and to honor fully Stanford's obligations. The city contract, signed in 1968 when Stanford purchased Palo Alto's holdings in the hospital, contains provisions relating to the organization of the medical staff.

In addition, the board said it would consider extending eligibility for privileges in these services to physicians who become extensively involved in teaching and research in affiliation with the School of Medicine under the direction of the faculty.

The board said it recognized that a closed staff policy may be a serious problem for community physicians who specialize in fields encompassed by the hospital-based clinical services, and for a full-service group medical practice such as that of the Palo Alto Medical Clinic which wishes to have full access to a well equipped hospital.

However, the board said it was persuaded by arguments that "a closed staff policy is essential to the successful. . .research and teaching missions of the School of Medicine."

The board commented that at Stanford University Hospital the open and closed staff concepts in hospital-based clinical services are mutually exclusive.

"While it would be possible to construct a compromise position between an open and closed staff policy, the board is convinced that no compromise is available which would serve the objectives of both a closed and an open staff.

"Any compromise would probably serve the objectives of neither position. The board. . .must choose between the two opposing positions."

The board gave these reasons for endorsing a closed staff policy in the hospital-based clinical services:

- more -

• Stanford acquired Palo Alto's interest in the hospital to enhance the research and teaching missions of the School of Medicine. These activities are important in advancing medical knowledge and improving medical care locally, nationally and internationally and are enhanced by a closed staff rule. The hospital is required by its articles of incorporation and bylaws to support these missions.

• The board was satisfied that a closed staff in these special services fosters high quality patient care.

• Hospital-based services in teaching and research hospitals are operated almost without exception under a closed staff restricted to medical school faculties. They are responsible for the design, acquisition, maintenance and operation of such services, and for the research and teaching programs conducted there.

• Stanford University or the hospital have no legal obligation to provide community physicians "an open-staff" hospital with respect to hospital-based clinical services. Nor do they have any "moral obligation to furnish such a hospital to community physicians when the research and teaching activities of the School of Medicine might be jeopardized."

The board said it conducted the review because no evaluation of staff privileges in hospital-based clinical services had been made since the city contract was signed. There were complaints from the medical staff, and a law suit concerning staff privileges in the division of diagnostic radiology was brought against the hospital by a community radiologist, Dr. William Hayden.

After the case was settled by Hayden's appointment to the medical staff, the board felt it could proceed with its review without concern about the impact of its findings on a pending law suit.

Of the 550 community physicians on the medical staff, 41 hold privileges in hospital-based clinical services.

"It is fair to state," said the board, "that during the past 10 years privileges with respect to these services have been granted sparingly to community physicians, and in many cases have been subject to limitations."

The board commented that it has also considered the hospital's "open-staff" policy that has existed for 10 years regarding admitting physicians.

"This policy can and should be continued at Stanford for the foreseeable future," the board declared. "The board does not contemplate any restrictions or limitations on membership or privileges in the admitting services for community physicians. . ."

In the future, however, the board indicated it might take steps to increase the involvement of community physicians and their patients in teaching activities.

Gullixson said "the board has carried out a very thorough review of a very difficult issue. It feels its decision is the best that can be made under the circumstances to further the teaching and community service roles of the hospital."

STANFORD—A vasectomy candidate should consider the operation permanent, says a Stanford urologist, despite the increasing number of reverse vasectomies.

"If a man does change his mind later, he must accept the fact that the reversal operation is still only about 25 to 33 percent successful," says Dr. Robert Kessler, assistant professor of surgery at Stanford University School of Medicine.

Vasectomy is a surgical interruption of the flow of sperm by cutting the tubes, called vas deferens, that carry the sperm.

Approximately 50 to 75 vasovasectomies, or reverse vasectomies, are performed at Stanford yearly. Because of recent microsurgical techniques to join the cut ends of the tubes together again, doctors will virtually assure that there will be sperm in the man's semen.

However, the pregnancy rate for women whose husbands have had a reversal is only about 25 to 33 percent.

The problem, says Kessler, is that men who have had vasectomies build up antibodies to their own sperm. The antibodies cause the sperm to either agglutinate or become immobilized.

Because many patients seeking the reversal surgery come to Stanford, doctors here have launched a study of antibody levels in patients prior to and following vasovasectomy.

Stanford is also one of the few centers in the country able to perform tests to detect these antibodies in the blood (called the Kibrick test for agglutination and the Isojima test for immobilization).

Antibodies are not normally formed because the sperm never reaches the blood system. After a vasectomy, however, they are absorbed into the blood through capillaries where they are treated as foreign to the body's systems.

With the antibody tests, researchers hope to be able to identify those patients with high levels of antibodies prior to surgery.

Kessler also hopes that future research will develop methods and/or medications to reduce the number of antibodies formed.

It is still not known, he says, whether the production of antibodies may be only a temporary condition.

Despite the odds for success, many more men are requesting the reversal surgery, says Kessler. He sees that as an effect of people considering the procedure reversible.

The most common reason men seek reversals, he says, is because they have been divorced and remarried and want to have children with their new wife.

The reversal surgery takes about an hour to perform, and is generally done on an outpatient basis. Sutures finer than human hair, used with the aid of a magnifying lens, have greatly improved the operative procedure.

But because the reversal may not work to cause a pregnancy, Kessler says "the most important advice for vasectomy candidates is to consider the operation permanent."

STANFORD—A concert featuring pianist Corinne Barkin will be held Saturday, Oct. 14 at Stanford in memory of the late Dr. Judith Graham Pool, noted Stanford hemophilia researcher.

Mrs. Barkin, a friend of the researcher, is a well-known Bay Area pianist. She will perform works by Liszt, Ravel, Scriabin and Beethoven, at 8 p.m . in Dinkelspiel Auditorium.

Proceeds from the concert and any additional donations will go to the Judith Graham Pool Fund to support students and physicians studying in the field of hematology.

Dr. Pool was professor of medicine at Stanford at the time of her death in 1975. She was internationally known for developing a simple method for extracting from normal blood the protein needed by hemophilic patients.

Availability of the missing clotting factor has enabled hemophiliacs to treat themselves at home with injections, reducing both the length of hospitalization and treatment costs.

She had also been active in promoting opportunities for women in medicine.

The Pool Fund, comprised of private contributions, is administered by Dr. Stanley L. Schrier, professor of medicine and head of the division of hematology at Stanford.

Mrs. Barkin, a resident of Menlo Park, studied at the Juilliard School of Music and Oberlin Conservatory, and has a master of music degree from the Manhattan School of Music. She performed at Carnegie Hall before moving to the Bay Area.

Concert tickets are available at all leading ticket agencies.

EDITORS: Photo available upon request if not included with story.

STANFORD—In school, simple tasks such as figuring out what an assignment requires, how to write an outline, and how to organize a report can be stumbling blocks to the person with a speech and language problem.

Sometimes, children with learning disorders are given special class placement. Those who don't require special classes may not get the extra attention they need.

For these children with underlying developmental speech and language disorders, an academic tutoring program is now underway at the Stanford speech and language clinic.

The tutoring program differs from usual clinic therapy. The focus is on specific learning problems children bring from school, such as homework or concepts they cannot understand, says Donna Dagenais, director of the clinic's preschool.

"These children need repetition. They need more than the average amount of practice in order to apply new things which they learn," says Dagenais.

Jeffrey is one of several children who are benefitting from the new program.

Jeffrey first came to the Stanford speech and language clinic with language difficulties when he was two-and-a-half.

After many months of individual and classroom attention, his therapists recognized that he still would be a high risk case in school.

In kindergarten and first grade, learning demands grew and Jeffrey had difficulty associating sounds with letters and coordinating the skills required in writing. His mother arranged for additional private tutoring.

"Fortunately, Jeffrey's tutor was tuned in to the language aspects inherent in learning tasks," explains Dagenais. Now he is doing well, and is entering third grade.

Dr. Kathryn Beadle, director of the clinic, says that speech and language disabilities often show up as learning disorders in school. Many children with such learning disorders need supplemental help intermittently throughout their school careers, she adds, and tutoring of the kind Jeffrey received at Stanford can make the difference between success and failure in school.

"Reading and writing are simply extensions of a child's oral speech development. If speech does not develop normally, the child is faced with trying to learn to read unfamiliar sounds and words. Learning to understand speech and to talk are the primary prerequisites to learning to read and write," says Beadle.

Amanda, a bright young student of 16, had been in speech therapy for articulation since kindergarten.

She was highly motivated in school, according to Dagenais, and worked long hours, often finding it necessary to read assignments many times in order to grasp the words and ideas.

She was able to get passing grades because of her diligence, but her understanding was poor, and her limited success only masked the depth of her problems, says Dagenais.

Amanda will enter the tutoring program this fall. Meeting her specific needs, her tutor will emphasize reading comprehension and "school survival skills," says Dagenais.

Amanda's tutoring will also include some career guidance and help in decision-making. She recently became a cheerleader at her high school, her first extracurricular activity. But she is intent on keeping up with her work and maintaining good grades, since she is determined to attend college.

Clinic staff members involved in the tutoring program are Kathleen Jacobson, who has a masters degree in learning disabilities, Dagenais and Shirley Nanevicz, both of whom have primary training in speech and language pathology and also have credentials as learning disabilities specialists, and Beadle, director of the clinic.

STANFORD—What causes arthritis?Which patients benefit most from total joint replacement? How can bone and muscle infection be effectively treated and prevented?

These and other questions are being studied in a new orthopedics research laboratory at Stanford University School of Medicine.

Research at the laboratory is supported by grants from the National Institutes of Health, the Arthritis Foundation, and the Orthopedic Research and Education Foundation.

The laboratory is equipped with complete tissue culture, microbiology and biochemistry facilities. A computer terminal which ties into eight other arthritis centers across the U.S. is available for data studies. Animal studies are performed at the laboratory, but patient studies are done in the orthopedic surgery clinic.

The laboratory brings together the expertise of orthopedic surgeons, immunologists, biochemists, computer scientists and mechanical engineers to search for better treatment and prevention of this debilitating joint disorder and the complications of surgery, said laboratory director Dr. David Schurman.

"Arthritis means inflammation of joints," he said, but it also involves destruction of cartilage.

Inflammation can be reversed by drugs, but once the cartilage is destroyed, it never can repair itself, he said.

It is still not known what causes arthritis, and why some people get it while others don't. But the inflammatory and destructive processes of the disease seem to be related to the body's immune system.

Recently, workers in the division of immunology found that radiation treatments of the lymphoid system can prevent the progress of arthritis in experimental animals.

Radiation, particularly to sites of lymphocyte (white blood cell) production, can "shut off the inflammatory processes and stop further development of arthritis in these animals," said Schurman.

The radiation technique was developed by Dr. Henry Kaplan, D'Ambrogio professor of radiology, to treat lymphomas. Kaplan and Dr. Samuel Strober, assistant professor of immunology, also are applying the technique to prevent rejection of transplanted tissues in experimenal animals.

- more -

Lyle Swenson, Jr., a research associate in mechanical engineering, is developing a computer model which describes in mechanical, electrical and chemical terms the strength of cartilage. With the model, Swenson can predict which biochemical event is necessary for the destruction of cartilage.

Biochemists under the direction of Dr. Robert Lane Smith, associate laboratory director, are studying the mechanism of cartilage breakdown to improve Swenson's model, and to develop new methods of preventing and treating arthritis.

"Over 130,000 total hip and knee joint replacements are performed each year in the U.S. alone," said Schurman, an orthopedic surgeon who performs these operations regularly. Yet it is not known which patients benefit most from surgery, he said.

To solve this problem, Stanford is developing a prototype data base on patients with arthritis related to the impact of surgery.

The data base will tie into ARAMIS (American Rheumatism Association Medical Information System), a data base covering the area of internal medicine in arthritic patients and directed by Dr. James Fries, associate professor of medicine.

The Stanford Arthritis Center is conducting a survey of patients with rheumatoid arthritis to evaluate the medical and social costs of the disease and the effectiveness of different treatments.

"If the data base is successful," said Schurman, "we will be better able to define the risks of surgery, for example. The physician will be in a much better positon to decide which, if any, operation is best for the patient."

Age, weight, height, sex, diagnosis and percent involvement of the disease of a particular patient can be matched with 30-50 similar patients from the computer within minutes. The outcome of these patients, compared to the average patient, can be calculated.

Infection is one of the leading causes of failure of total joint replacements, noted Schurman. "It is more catastrophic than other complications."

The orthopedics research laboratory is "one of the few centers in the U.S. where musculoskeletal infections related to surgery are studied," he said.

One study led to improvements in the use of bone cement, the substance used to attach artificial joints to the skeleton. That study won a $1000 award from The Hip Society earlier this year.

Other studies include the pharmacology of antibiotics and the mechanism of joint infection, which is providing information about the development of inflammatory arthritis, Schurman noted 312

STANFORD—Too much salt is bad for your health, says a Stanford physician.

Everyone, not just those with high blood pressure, should lower their salt intake by two-thirds, said Dr. John W. Farquhar, professor of medicine and director of the Stanford Heart Disease Prevention Program. He made his remarks in testimony prepared for delivery Monday, Sept. 25, before the Select Committee on GRAS (generally recognized as safe) Food Substances.

The Committee, meeting in Bethesda, Md., is evaluating the safety of salt as a food ingredient, and will make recommendations to the Food and Drug Administration. Farquhar is a member of the executive committee of the American Heart Association (AHA) Council of Epidemiology, and of the nutrition committee. He spoke as a representative of the AHA.

"Cardiovascular disease risk is a function of blood pressure at all pressure levels," he said, and lowering salt intake lowers blood pressure in a wide range.

The benefits, therefore, would affect the majority of Americans, including those with blood pressures in the "normal," but still higher than preferred, levels.

Hypertension, he said, is not a problem with clear distinctions between normal and abnormal levels of blood pressure.

Farquhar called for a gradual and phased approach to lowering salt intake from current levels of 12 gramsay to 4 gramsay.

He said studies have shown that moderate limitation of salt intake to 4 gramsay resulted in important reductions of blood pressure among hypertensive patients. He called this level "quite readily achievable in this country," which could be maintained without hardship or loss of palatability.

"We recommend that public health education be the main method of attaining this goal," said Farquhar.

He described Stanford experiments that tested individual's abilities to "step down" their salt intake. In those studies, "adults with mild hypertension were readily trained to prefer lower salt levels after a few weeks of graduated withdrawal."

Farquhar reported that moderate decreases in salt intake were achieved following a two-year health education campaign in three Northern California towns to reduce heart disease risk factors. In that project, called the Stanford Three Community Study, the salt decreases "were the strongest predictor of blood pressure lowering among the factors observed."

With a gradual approach, Farquhar noted, the "natural demands for lowered salt products would create opportunities for food producers."

The AHA, he said, also recommends that labeling of salt contents of processed food should become a common practice.

In addition, he said, the AHA is planning to support public health education about salt intake, and teach ways to prepare low salt meals.

STANFORD—Many more patients with hardening of the arteries could benefit from advances in vascular surgery, according to Dr. D. Craig Miller of the Stanford University School of Medicine.

Because of a communications gap within the various specialties of the medical profession, sizable numbers of these patients are not being referred or referred to late to vascular surgeons, said Miller.

Vascular surgery refers to operations on the blood vessels. It has become more important as life expectancy increases and more patients develop atherosclerotic conditions. Today developments in arterial grafts and arterial reconstruction make it possible to treat pativnts for problems which were considered insoluble in the past.

"Vascular surgery can save limbs, extend productivity and life expectancy, ameliorate hypertension (high blood pressure), and prevent stroke more reliably and with less risk than ever before," Miller said.

Miller's comments were made in a report scheduled for publication in the Sept. 29 issue of the Journal of the American Medical Association. His article is co-authored by Dr. Randall B. Griepp, formerly of Stanford and now chairman of the department of surgery at the State University of New York Downstate Medical Center in Brooklyn. Miller is assistant professor and chief of cardiovascular surgery at the Palo Alto Veterans Administraton Hospital.

Many primary physicians, general internists and cardiologists simply are not fully aware of the rapid advances that have been achieved in peripheral vascular surgery during the past ten years, said the surgeon.

"As the subspecialty of vascular surgery has matured, it is incumbent upon general physicians and vascular surgeons alike to develop appropriate channels that can transmit clinical concepts, educational information, and clinical results as well as patient referrals," Miller said.

Many more patients, for example, could benefit from surgery to replace blocked arteries in the legs, he said. "Vascular surgery for limb salvage as an alternative to amputation should be considered in all cases," Miller said.

He cited "surprisingly good" 50 to 70 percent five-year limb salvage rates now being reported from major vascular centers.

Other procedures in which surgeons have become adept concern the treatment of high blood pressure caused by hardening of the renal (kidney) arteries. Some renal arteries which have become obstructed can be bypassed by the application of a bypass graft. Such a graft is attached above and below the obstruction in the clogged artery to restore normal or near normal blood flow.

In cases where many small vessels are occluded the kidney can be temporarily removed from the patient, the vessels repaired and then reimplanted.

Current operative risks for renal artery reconsruction are about 1 percent for those patients without generalized atherosclerosis and 5 percent for those afflicted with generalized disease, Miller said.

Before the advent of successful vascular surgery, many patients with atherosclerosis were forced to lead restricted, incapacited or shortened lifes, he said.

STANFORD—Women with high risk pregnancies who are likely to go into premature labor, now are arriving at Stanford Hospital in emergency air ambulances much more frequently than in the past.

During 1976, the hospital accepted 12 maternal transports. This year, to date, 66 mothers have been received, says Dr. Kent Ueland, professor of gynecology and obstetrics at Stanford Medical School.

"We would like to avoid complicated transports involoving newborn premature infants whenever possible," says Ueland, who views the rise in numbers of maternal transports as a good trend.

It is advantageous for both the mother and the infant if the premature birth occurs in a hospital with a well-equipped intensive care nursery rather than during transport or at a facility unprepared to handle premature infants, he says.

Dr. Jan Ehrenwerth, assistant director of the Northern California Medical Infant Dispatch Center agrees that transport of the mother is preferable to transporting a newborn premature infant, despite sophisticated equipment now available for care of such infants.

"Mother is still the best incubator," he says.

The dispatch center coordinates both maternal and newborn transports throughout northern California between the Oregon border and the Tehachapi mountains.

The center keeps track of bed availability in 10 intensive care nurseries in northern California hospitals, coordinates travel arrangements for the emergency infants and mothers, and maintains close air to ground communication with the transport units during emergency flights.

Some of the hospitals in the network, including Stanford Hospital, allow the woman's private obstetrician to accompany her and deliver the infant at the receiving hospital, says Ehrenwerth.

State funding to the dispatch center has just been renewed and will continue through June, 1979.

STANFORD—Group therapy for patients with advanced cancer can be exceptionally effective, two psychiatrists have learned after five years of working with cancer patients at Stanford University Medical Center.

Patients in the group were helped by helping one another, and by finding they have much of value to share and to teach, according to Drs. David Spiegel and Irvin D. Yalom writing in the International Journal of Group Psychotherapy.

"We believe," said Yalom, "that group therapy is a valuable modality for the treatment of terminally ill patients and that much can be learned from such groups for the everyday therapy of the living."

The Stanford program began in an effort to provide emotional support for cancer patients. "We assumed that the group members would profit from continued close contact with others facing the same tragic experience," said Yalom. "Sharing, open communication, and the opportunity to be helpful to others would be an antidote to the bitter isolation experienced by dying patients."

Initially, the group was made up of patients with breast cancer which had spread. Now, however, under a gift from a former patient, the late Mrs. Eva L. Goitein of Belmont, the group has been expanded to include patients with all forms of metastatic cancer.

The meetings are held Mondays from 1:30 to 3 p.m. in Stanford's Department of Psychiatry and the Behavioral Sciences. Participation is free of charge. According to Drs. Spiegel and Yalom, the therapists and the group members worked together to determine the direction of the program.

They met weekly for 90 minutes. At times, special one-hour sessions preceded the group meetings during which training in self-hypnosis or meditation had been offered.

The group was open and members could come as often as their physical condition permitted and as long as they continued to benefit from participation.

Most were outpatients, and some attended while they were hospitalized. The number of patients attending the meetings averaged six to seven.

- more -

"We have found the maximum effective size is seven," said Spiegel and Yalom. "When more than eight members have attended, we have often divided the patients into two small groups for an hour and reconvened as a large group for the final 30 minutes."

The psychaitrists have recorded variations in the responses of group members to their experience with the therapy. But they also found striking similarities in the results among them.

"There is, in general, a decrease in denial about having cancer," said the psychiatrists. "Time is seen as precious, too precious to be wasted on unwanted social commitments or 'pleasing others.'

"Very often the women have felt they were treated as objects by their physicians and they were not given the information they felt entitled to have.

"Many patients reported improved communications with their doctors, and several of the women who had been engaged in constant struggles with their husbands reported they had made major improvements in their marriages."

Some patients, the psychiatrists said, reported improved communication with their families. Others with less rewarding family ties used the group as an alternative to counter their sense of loneliness and isolation.

"Many patients found new meaning in their lives in the sense that how they lived the remainder of their lives became important and how they died came to seem insignificant," concluded Spiegel and Yalom. "They were able to plan and live with an enhanced sense of meaning and dignity."

Patients have entered the Stanford program by referral from other patients or from organizations such as the American Cancer Society.

"At first, physicians were reluctant to refer patients to the program from fear that a group which discussed death and dying would severely unsettle them," the authors noted. "However, after observing that the group was life-oriented and that patients found it enormously supportive, many physicians have sent their patients."

Over 50 patients have participated in the program since its inception.

Patients with advanced cancer may obtain information about the program by calling the Department of Psychiatry and Behavioral Sciences at Stanford, Tel. 497-6352.

STANFORD—The Center for Integrated Electronics in Medicine at Stanford University has been awarded a $4.6 million five year grant by the National Institutes of Health to "continue to study the applications of this advanced technology in preventing, identifying and treating disease," according to center director Professor James D. Meindl.

The center, one of three in the U.S. established by the NIH in 1974, combines the expertise of electrical engineers in the Stanford Electronics Laboratory (SEL), and physicians at the School of Medicine in designing electronic instruments for use in a wide range of medical fields.

Current projects of the center include the development of an ultrasonic imaging system in ophthalmology, a Doppler shift flowmeter, and implantable telemetry systems.

High frequency sound waves used in the ophthalmic imagery device enable doctors to "see" into and behind eyes which have become clouded by cataracts, hemorrhaging or detached retinas.

The device, which consists of 35 transducers in linear array, produces a moving picture of the eye on a video screen without moving itself. Most ultrasound devices must be moved across the surface being scanned.

Because it remains motionless, this new device can safely be used to examine damaged eyes and those of very young children and elderly people. It is currently being tested in patients at Stanford hospital.

"This device is the first of its kind," says Dr. Alan Susal, clinical assistant professor of ophthalmology, who produced it with Drs. Roger Melen and Terry Walker of the SEL.

"It represents the culmination of several years of work on integrated circuits in medicine, and it shows that the engineers here can build a superb clinical instrument as well as advance the state of medical diagnosis," he says.

- more -

Ultrasound devices which can examine the heart and abdomen also are being developed at Stanford. One device, developed by Levy Gerzberg and Charles Hottinger in the SEL, detects the velocity of blood flowing through vessels by bouncing high frequency sound waves off red blood cells.

The echoes, or returning sounds, change in frequency depending on the velocity of blood flow. This is known as the Doppler shift principle.

The flowmeter is being prepared for testing in patients by Drs. Thomas Nelsen of the Department of Surgery and William Brody of the Department of Radiology. It provides a noninvasive alternative to placing catheters in blood vessels to measure flow, a procedure which can be risky in some patients, says Meindl.

Drs. Donald Harrison and Jerry Griffin the division of cardiology at the Medical School are using biotelemetry to study the response of the heart to drugs and other environmental conditions such as stress. Biotelemetry is the transmission of physiological information by radio waves.

Transducers, developed by Drs. James Knutti and Henry Allen in the SEL, are implanted in the heart and blood vessels of experimental animals, and transmit up to six different cardiovascular values, such as blood flow and pressure, continuously.

Stanford is well suited for investigations of electronics in medicine, not only because of its strength in medical research but in electrical engineering as well, says Meindl.

Stanford is one of the leading universities in electronics research (others include MIT and University of California at Berkeley), and it draws from the rich industrial expertise of the Santa Clara Valley, he says.

"We therefore have a poweful capability to serve medical users," he says. "Integrated electronics can be of enormous benefit to the quality and availability of health care. We feel it is important to make a contribution."

STANFORD—Research at the Stanford Outdoor Primate Facility is changing directions this fall.

The study of chimpanzees in this semi-natural setting on Jasper Ridge, just west of the Stanford University campus, is being discontinued in favor of study of other monkey species.

The decision of move the chimps was made because of difficulties in handling these large primates and limitations in the data which can be collected, according to facility director Dr. Seymour Levine.

Levine and other members of the Department of Psychiatry and Behavioral Sciences met last week with Provost William Miller and other university administrators.

The ultimate fate of the chimps has not yet been decided, although Levine said he would like to see them moved and kept intact as a breeding group elsewhere.

In a memorandum to public affairs director Robert Rosenzweig, Levine suggested the facilities be used to house groups of Rhesus macaques for breeding purposes, and to "permit intense investigation of the biology of social behavior and developmental problems."

Last year, several Asian countries banned the export of Rhesus and other monkey species, seriously curtailing their availability for research.

In addition, the macaques are smaller in size and breed faster than chimpanzees, making them easier to handle and study.

"Although we have made considerable progress, and have produced data that are interestng in terms of understanding chimpanzee behavior, we believe that in the future the program will have diminishing returns," he said.

Studies of the relationship between hormones and behavior are stymied by the great difficulty in obtaining blood samples from the animals.

"Chimpanzees are very unpredictable," said Levine. They can be dangerous in an enclosed setting and must be anesthetized prior to taking blood samples.

"The trauma involved in obtaining samples is so great as to make any conclusions regarding the relationship between levels of circulating hormones and behavior meaningless," he said.

As an alternative, hormone studies are being conducted in squirrel monkeys, which are much smaller and therefore easier to handle than chimps.

The Stanford Outdoor Primate Facility was originally conceived by Dr. David Hamburg, former chairman of the psychiatry department and now president of the Institute of Medicine of the National Academy of Sciences.

- more -

The facility was established in 1974 to provide a "simple psychobiologic evolutionary model of human behavior," in conjunction with studies at the Gombe Stream Research Center in Tanzania by world-famous ethologist Jane van Lawick-Goodall, said Levine.

The facility would also provide training for students who wished to do research at the Africa field station.

But in May, 1975, four of the Stanford personnel at the station were kidnapped by Zaire guerillas. Although they were later released unharmed, the Tanzanian government closed the facility to all students and scientists except Goodall.

Further problems plagued the chimpanzee program. Three of the original 17 animals developed serum hepatitis and had to be removed from the group. Five infants have died this year, three of the deaths occurring at birth.

"These losses have, at least for the moment, impaired research on mother-infant relations," said Levine.

In 1976, the chimps received attention from suggestions of Stanford researchers that they may be able to predict earthquakes.

Prior to a single swarm of minor earthquakes in June, 1976, the animals were observed to be more restless than usual, and spent more time on the ground than on climbing structures and nesting areas.

However, the facility does not experience enough isolated quakes to confirm the hypothesis, and the studies remain incomplete.

Currently, Levine is studying social behaviors among squirrel monkeys in his laboratory at the Medical Center. He has found that certain social behaviors in these monkeys are determined by the environment.

For instance, the initiation of sex behavior by the male monkey depends on the level of estrogen in the female, and has nothing to do with testosterone levels in the male. "The male is synchronized by the female," said Levine.

During the establishment of hierarchy among squirrel monkeys, the leader has higher levels of testosterone, but when the struggle is over, he has no more than any other group member. "Dominance alters testosterone levels, not the other way around," he said.

"Some behaviors are under rigid biological control, while others are more influenced by the environment. This suggests the importance of the group in integrating the behaviors of its members," he said.

These studies are providing information about social interaction among humans. Recent evidence by other investigators indicates that hormones may play a role in human status rank behaviors.

STANFORD—Catecholamines, the brain chemicals involved in a wide range of human behaviors, will be the subject of an international conference at Asilomar in Pacific Grove, California September 18-22, 1978.

The press is invited to attend the meeting, which draws 750 scientists from around the world, including East Europe and Russia.

The meeting is sponsored by the National Institute of Mental Health (NIMH) and by the Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine.

"Catecholamines are a remarkable class of compounds which includes adrenaline, noradrenaline and dopamine," says Dr. Jack Barchas, director of the Nancy Pritzker Laboratory of Behavioral Neurochemistry at Stanford.

These compounds carry electrical impulses across the gaps, or synapses, between nerve cells. For this reason they are called neurotransmitters.

The theme of the conference, says Barchas, is frontiers in basic and clinic science.

"Basic science has repeatedly resulted in major progress in the clinical arena," he says. For instance, dopamine was discovered in the brain only 20 years ago. Today, dopa, a natural precursor of dopamine, is used to treat Parkinson's disease, which results from a deficiency of that neurotransmitter.

In addition, knowledge of catecholamines has revolutionized treatment of patients with severe mental illnesses such as schizophrenia and depression. The development of effective drug therapies during the last 25 years has enabled many patients to leave the hospital and be treated in the community.

Among the papers presented during the five-day conference are studies of the role of catecholamines in severe mental illnesses, in hypertension, in nerve growth factor and in alcoholism.

Nobel laureate Julius Axelrod of the NIMH will report on the concept of receptor control. Receptors are chemical sites on the ends of nerve cells through which neurotransmitters exert their effects. Regulation of receptors is an important factor in chemical transmission.

Other NIMH participants in the conference include Dr. Irwin J. Kopin, conference chairman and director of the Laboratory of Clinical Science, and Dr. Earl Usdin, of the Psychopharmacology Research Branch.

STANFORD—A new course on sports medicine will be offered this fall at Stanford University Medical School.

Designed by Dr. Alfred Spivack, clinical professor of medicine at Stanford, the course will examine medical aspects of exercise covering a wide range of physiologic conditions.

Spivack feels that physicians should have adequate knowledge of sports in order to advise their patients about exercise. He adds, "the emphasis will be on the basic physiology, proper training and conditioning, and the importance and selection of proper equipment."

The course is not designed to cover treatment of sports-related injuries. Spivack primarily hopes to encourage safe participation and enjoyment in sports.

Noted physicians from Stanford will present lectures on a variety of topics in their areas of expertise.

Classes will be taught by the following faculty members.

• Exercise physiology—Dr. William Haskell, clinical assistant professor of medicine and well known exercise physiologist.

• Endurance sports—Dr. Peter Wood, adjunct professor of medicine. Wood is writing a book on endurance sports, and he is a marathon runner himself.

• Fluid balance and nutrition—Dr. Roy Maffly, professor of medicine, expert on fluid and electrolyte balance.

• Altitude sports—Dr. Herbert Hultgren, professor of cardiology and noted researcher in the area of altitude-related health problems.

• Racquet sports—Dr. Kenneth Campbell, clinical assistant professor of surgery and author of a textbook on tennis injuries.

• Contact sports and other land sports—Dr. Richard Swett, clinical instructor of surgery and orthopedic surgeon trained in sports medicine.

• Underwater sports—Dr. Alfred Spivack, diving enthusiast and organizer of the course.

The new course is scheduled to meet on Fridays from 3 to 4 p.m., and it will be open to medical students and human biology students.

STANFORD—Dr. David A. Prince, chairman of the department of neurology at Stanford University School of Medicine, is the 1978 recipient of the Lennox Award given by the American Epilepsy Society "in recognition of his important contributions to the field of epilepsy."

Prince received the $2500 prize September 11 at the annual AES meeting in Vancouver.

Prince, 46, has been studying epilepsy since the early 1960s in an effort to understand the cellular processes involved in the disease, and to apply this knowledge to the problems of patients.

Epilepsy is a symptom of abnormal brain activity caused by excessive electrical firing of groups of nerve cells. These cells can set off an "avalanche" of firing involving large areas of the brain and resulting in seizures or convulsions.

The disease afflicts an estimated three million Americans. Anti-epileptic drugs are available, but they can control the symptoms effectively in only 60 percent of the cases.

In 1971, Prince and his colleagues at the Max Planck Institute in Munich, Germany reported the first accurate measurement of changes in potassium levels during the course of epileptic activity using highly sensitive microelectrodes.

Electrically charged molecules, or ions, of potassium are involved in the conduction of electrical signals down the long arms of nerve cells, the axons.

Three years later, Prince and his associates at Stanford found that there was a local potassium build-up in the spaces between nerve cells during experimental epilepsy which could reach three to four times normal levels.

Recently, the Stanford group has been studying calcium, another ionic salt involved in electrical and chemical transmission.

According to Prince, changes in both calcium and potassium ions could act upon the nerve membrane to "increase excitability and cause the nerve cell and its axon to fire repeatedly."

The results of recent experiments by the Stanford group, reported at the Vancouver meeting, provide new evidence for these ionic effects, says Prince.

In 1976, Prince and his associates reported the first measurements of electrical activity from within a single living human nerve cell.

- more -

The recording was accomplished by inserting microelectrodes into slices of brain tissue which has been surgically removed as part of the treatment for epilepsy. The tissue was kept alive in a special chamber containing a solution of salts, sugar, and oxygen.

"This technique will allow us to identify exactly those cells which are involved in epileptic discharge," says Prince. By studying the same cells under the microscope, "we will be able to decide whether they differ structurally from normal nerve cells," he says.

Using similar techniques and animal brain tissue, the Stanford group has been able to produce experimental epilepsy in brain slices by treating them with chemicals, ions or drugs.

"Studies of the behavior of nerve cells in these brain slices have led us to propose that cells have a potential for generating epileptic discharges which is normally inhibited," says Prince.

Certain drugs and chemicals seem to remove this inhibition, resulting in excessive bursts of activity. The development of epilepsy after a brain injury may also be related to removal of nerve cell inhibition, he says.

Recently, Prince and his colleagues have begun to study how anti-epileptic drugs act. "We don't know if these drugs work differently in normal and epileptic cells," he says.

It also is not known whether chronic drug use produces changes in nerve cell activity, particularly in the developing nervous system. In many instances, epilepsy begins during childhood, and affected children may take drugs for several years.

"These studies could improve our knowledge of how existing drugs work, and lead to the development of new drugs that might be useful," says Prince.

Prince, a graduate of University of Pennsylvania School of Medicine, has been at Stanford since 1963. He has published widely, and has received numerous grant awards in support of his research, including a Guggenheim Fellowship in 1971.

STANFORD—Dr. Kenneth L. Melmon, professor and chairman of the Department of Medicine at Stanford University Medical School, has been appointed to the Arthur L. Bloomfield Endowed Professorship.

Melmon, 44, is an internationally known clinical pharmacologist. He heads the medical school's largest department, which includes 12 divisions, and has responsibilities for the clinical medical training of medical students, housestaff physicians and postdoctoral fellows.

He became department chairman on Sept. 1, succeeding Dr. Daniel Federman, who is now at Harvard Medical School. Federman previously occupied the Bloomfield endowed chair.

A Stanford undergraduate, Melmon received his M.D. from the University of California in San Francisco (UCSF), and prior to joining Stanford he was a professor of medicine and chief of the Division of Clinical Pharmacology at UCSF.

His research has led to 195 publications, including editorship of a recent edition of *The Pharmacological Basis of Therapeutics*, a textbook in the field.

Melmon is recognized as one of the founders and leading figures in the field of clinical pharmacology. He was elected president of the American Federation for Research in 1973-74, and president of the American Society of Clinical Investigation for 1978-79.

At UCSF Melmon and his associates identified the chemical receptors for histamine on the surface of white blood cells. They also developed important new concepts concerning relationships between immune and inflammatory processes and their regulation.

The Arthur L. Bloomfield Professorship honors one of Stanford's most distinguished physicians.

Bloomfield retired as head of the Department of Medicine in 1954 after 26 years on the Stanford Medical School faculty. He continued to serve as director of the historical collection at the school's Lane Medical Library until his death in 1964.

STANFORD—Stanford University School of Medicine faces a potential loss of up to $2.3 million in Medicare payments this year, according to Dr. Clayton Rich, vice president for medical affairs and dean of the school.

Rich said the problem was the result of new guidelines by the Department of Health, Education and Welfare concerning the professional fees of teaching physicians.

Under the new ruling, professional fees of salaried faculty physicians that are turned over to the medical school to support operations are treated as restricted funds, and must be deducted from Medicare claims.

"Stanford does not agree with this interpretation," said Rich, "and it will be evaluating various steps to obtain appropriate reimbursement for its services".

He emphasized that professional fees of faculty physicians are not restricted and are commonly employed to support a wide variety of medical school programs.

Previously, the medical schools could claim part of faculty salaries from Medicare in their institutional costs. This was the portion of faculty time devoted to teaching interns and residents. However, the amount of the claim had to be reduced to the extent that there were funds such as grants and gifts restricted to paying faculty salaries. The effect of the new interpretation is to classify physicians fees among these restricted funds.

Stanford has a medical practice plan which is similar to those of many medical schools. The physicians are salaried by the School. Their professional fees are turned over to the medical school fund, and distributed to departments and the school's reserve.

Rich said Stanford was informed two weeks ago that most or all of the expenses in its 1977-78 claim for institutional cost recovery come under the new interpretation.

The $2.3 million figure is an estimate, he said, based on Stanford's preliminary understanding of what costs will be influenced by the ruling. It will be modified by the time Stanford's claim is submitted in November.

However, until the matter is clarified, "we will not be able to spend any of the $2.3 million previously expected," Rich said. "This will create very serious difficulties for the clinics and the medical school."

The loss of income will have immediate impact on departmental funds, and will cause in the medical school an operating budget deficit of nearly $900,000 for fiscal 1978-79, he said.

Stanford received information about Medicare's new policy in April. Several university medical centers, including Stanford, asked for clarifications. Blue Cross of Northern California, the fiscal intermediary for Medicare, obtained the answers from the Medicare Bureau in Washington, D.C. two weeks ago.

Stanford's faculty practice plan is currently under investigation by the Board of Medical Quality Assurance on grounds it may be in conflict with a section of the state's business and professions code, and by Medi-Cal because of allegations of double billing.

Medical school officials have denied the allegations, pointing out that the faculty practice plan is in use in about half of the nation's medical schools.

However, Stanford is concerned, they said, about these investigations and has employed Arthur Andersen Co., an accounting firm, to make an independent assessment of the billing practices in the hospital and clinics.

Faculty practice plans also have been the subject of national attention in recent months, according to the Association of American Medical Colleges. The plans are caught in the conflict between the federal government attempting to head off escalating health care costs, and the medical schools that rely on faculty income as an essential support of medical school programs.

An AAMC study, released last year, shows that income from such plans provides vital support for medical faculty compensation.

CITY DESKS: Photo available upon request if not included with story.

STANFORD—Childbirth—an exhausting and exhilarating experience for most parents—can be transformed into uncertainty and fear when parents learn their newborn is ill.

Infants born prematurely may suffer from severe respiratory distress or heart disease. Others may have birth defects such as Down's syndrome (mongolism), spina bifida (malformation of the spinal cord) or hydrocephalus.

Stanford University Hospital has developed a special program to help parents cope with these problems.

The intensive care nurseries at Stanford serve an area extending from the Oregon border to the Tehachapi mountains. Approximately 1,000 critically ill infants are admitted each year.

When a child is born with a congenital illness or abnormality, explains pediatric social worker Rose Grobstein, parents often react with disbelief. Later they may ask, "Why did it happen to me? What did I do wrong?" Both parents may become depressed. If the disability is severe and cannot be corrected they may secretly wish for the death of the infant.

The Stanford program provides professional counseling to help parents resolve feelings of grief and guilt. It assists them in planning for future care of the child and encourages them to help one another through mutual support groups.

At Stanford there are self-help groups for parents of infants in intensive care, for those whose children have spina bifida and for parents of children who have died.

Twice a month, parents of children in the intensive care nursery meet in a nearby conference room. Attending one Sunday session were two couples from San Jose and Modesto, a mother and her parents from Santa Maria, Grobstein and nurse Dupi Gomez.

The setting was informal, the parents eager to talk about their children.

- more -

All three infants were premature. The child from San Jose had hyaline membrane disease, a respiratory ailment that afflicts babies whose lungs are not fully developed. The mother and child from Santa Maria had flown to Stanford by air ambulance. The couple from Modesto previously lost one child when it was 11 days old and another in a miscarriage. When the mother went into labor almost two months early, she was rushed to Stanford Hospital.

The babies were doing well, now. The parents, however, were "sitting on pins and needles." "We're hoping for the best, but expecting things to go wrong," confessed Susan Machado, the young mother from Modesto.

They listened intently to each other's story: the onset of labor, trip to the hospital, complications of delivery, and finally the birth itself. At one home a kindly neighbor, who had rushed over to care for the older children, fainted upon the kitchen floor moments after her arrival. They shared their fears. Each time the telephone rang—and it rang often as friends and relatives called—they wondered if it was the hospital calling.

And they shared their triumphs: the infant from San Jose had been transferred to the "Romper Room," a nursery for infants who are not acutely ill, but require long-term hospital care.

What was their reaction to the intensive care nursery, Grobstein asked. "They try to prepare you but still it's a total shock," said Robert Machado. "All the needles and blood...a slap in the face."

"I couldn't believe it," said a father when a nurse asked him to hold and feed the baby. To ease the trauma of hospitalization for parent and child, Stanford encourages parents to take part in the care of the infant.

"Nurses have to convince parents that their babies are not as fragile as they look," explained Grobstein.

The parents expressed satisfaction with the staff. "I admire their honesty and integrity," said Robert Machado. "They are right up front with you and tell everything like it is."

The meeting over, parents returned to the nursery and the waiting. As one mother said earlier: "The wait seems so long...like it will take forever for the baby to start growing."

How did the meeting help? "You learn about everybody else's problems, what other parents are going through," said Susan Machado. "At first you felt like you were the only one."

STANFORD—Three administrative appointments have been announced in the Stanford University School of Medicine by Dr. Clayton Rich, vice president for medical affairs and dean.

Effective immediately, David Mendelow will become associate dean for administration while David S.P. Hopkins will be assistant dean for administration.

Marion Knox will become assistant to the associate dean for faculty affairs.

Mendelow, 36, an associate hospital administrator since December, 1977, has been primarily responsible for the Stanford University Clinics and emergency services. He will continue to carry out his responsibilities in the clinics.

Hopkins, 35, has been a senior staff associate in the University's Academic Planning Office since 1975. He will direct academic and resource planning, and will be responsible for several administrative units within the medical school.

Mendelow came to Stanford from Arthur D. Little, Inc., where he was a senior consultant. He received the M.B.A. in health care administration from George Washington University, and held positions at the Albert Einstein College of Medicine and the Bronx Municipal Hospital Center in New York. He also served as project director for the programming of the 1,000-bed University Hospital at the Federal University in Rio de Janeiro.

Hopkins, a Harvard graduate, holds degrees in statistics and the Ph.D. in operations research from Stanford. He held posts as a systems analyst with IBM, the University of California, and was IBM postdoctoral research fellow in the Department of Operations Research at Stanford in 1971-72. His functions in the Provost's Office included budget planning, development of computer models for use in long range planning, and studies of such areas as faculty tenure and retirement planning.

Knox has served as administrative assistant in the dean's office of the Medical School since 1973. She is a graduate of Northwestern University, and has held posts in the School of Engineering at Stanford, and the personnel office of the University of Chicago Hospitals and Clinics.

STANFORD—Personnel working in many hospitals, dental offices and veterinary clinics are exposed to possibly harmful levels of anesthetic gases, because "all available measures to minimize levels of exposure have not been taken," according to Dr. Charles Whitcher, professor of clinical anesthesia at Stanford University School of Medicine.

"It is believed that most hospitals have installed scavenging equipment which vents excess gases from the anesthesia machine, but unless the air is monitored there is no assurance that anesthetic exposure is actually reduced," he says.

Whitcher will speak on the control of occupational exposure to inhalation anesthetics Friday, September 8, at the Stanford Anesthesia Conference in the Medical School's Fairchild Auditorium.

Chronic exposure to inhalation anesthetics is a suspected cause of several health problems, including spontaneous miscarriage, cancer, liver disease, and birth defects.

Slightly increased rates of these disorders were found among operating room personnel during a 1975 epidemiological survey conducted jointly by the National Institute of Occupational Safety and Health (NIOSH) and an ad hoc committee of the American Society of Anesthesiologists.

On the basis of the survey findings and lab evidence, NIOSH drafted a standards criteria document recommending universal use of all control measures. This document currently is being reviewed by the Occupational Safety and Health Administration (OSHA).

As yet no federal regulations regarding control of anesthetic gases have been formally enacted.

Exposure to anesthetic gases is not a proven health hazard, and contributory causes, such as stress, cannot be excluded, says Whitcher. But neither can the possibility of harmful effects of the gases be ignored.

In a preliminary study reported in 1975, Dr. Ellis Cohen and his associates at Stanford found increased frequency of liver disease among dentists using inhalation anesthetics more than three hours per week, and increased spontaneous abortion among their wives, compared to dentists who did not use the agents.

"Because the vast majority of dentists use nitrous oxide alone, it is likely that this is the causative agent," says Whitcher. A detailed study of dentists and their female assistants is currently underway.

Control of occupational exposure to anesthetic gases includes preventive maintenance of anesthetic equipment, leak testing procedures, and scavenging. Scavenging refers to the collection of waste gases at the anesthetic breathing system and their disposal outside of the building.

These techniques do not provide sufficient control. The amount of gas taken by the scavenging equipment, for instance, "may be an inconsequential part of the total level, depending on the presence of other sources," says Whitcher.

Control is assured only when the air is monitored."We have found significant leakage in several hospitals which could have been present since the buildings were first constructed," he says.

The basic air monitoring device, an infrared spectrophotometer, costs about $2,000, plus additional expenses involved with operating the instrument and record keeping.

The cost and sketicism about the dangers of anesthesia exposure may be reasons why many hospitals and dentists have not invested in monitoring equipment, says Whitcher.

STANFORD-The most outstanding feature of the Chinese is their personal cleanliness and freedom from many diseases which continue to plague Westerners, says Dr. Eugene Farber, chairman of the dermatology department at Stanford University School of Medicine.

"Venereal diseases have been virtually eliminated," says Farber, who recently returned from a three and a half week trip to mainland China. "So have malaria, cholera and other infective diseases spread by insects and rodents.

"There is no alcoholism in China, and no drug problem," he says. "The Chinese have a mania for cleanliness." Everything from the streets to the water they boil continuously, is immaculate, he says.

Farber and Dr. Robert Goltz of the University of Minnesota are the first dermatologists invited to China by that country's Academy of Sciences under a program of scientific exchange.

Their visit included tours of seven major cities, including hospitals, dermatology clinics, factories, agricultural communes, and historial sites.

During his visit, Farber met with Dr. George Hatem, the man credited with eradicating venereal disease in China in less than 10 years.

Hatem, a Lebanese who attended college in the U.S. and medical school in Switzerland, was a personal physician of the late Chairman Mao Tse-tung, and now is advisor to the Chinese Ministry of Medical Sciences.

Hatem came to China in 1939 to study tropical disease. He found a country ravaged by venereal diseases. An estimated three to five percent of city dwellers carried VD, and the incidence was as high as 10 percent in the war zones. Infectious diseases such as cholera, typhoid and dysenteries were epidemic, and had killed millions of people.

"I saw children dying in the streets," said Hatem during a visit to Stanford last week. Prostitution of both women and children was widespread, as was child labor.

"These things stimulated me to think about what it meant to be a doctor," he said. "I began to feel that medicine was not quite the answer to China's problems."

Accordingly, Hatem decided "to join the Red Army and fight for liberation." He dropped out of sight and would not return to the U.S. for 45 years.

(more)

After the revolution, Hatem became involved in the attack on infectious diseases. Since insects were known to carry disease, the people were organized in a massive insect-killing campaign. Today there are no insects in China.

Snails were known to carry schisto somiasis, a parasite which causes anemia, enlarged liver and spleen, and death among workers in the rice paddies. So the people killed snails. By the 1970s, 99 percent of the snails had been destroyed.

"There is a new sense of what we call in China 'socialist epidemiology,' " said Hatem. "Without any change in medical care, if you teach people not to take anything uncooked by mouth, to boil water, to keep their hands clean, your population will become immune to gastrointestinal infections."

Veneral disease presented a greater challenge, because it was spread by sexual promiscuity and prostitution. Its elimination required a change in the social system, said Hatem.

The change involved rounding up prostitutes of all known brothels, treating them medically, and indoctrinating them. They were given jobs, as laborers, as nurses, and as propagandists against VD. By 1966, venereal disease had been wiped out.

Today, sexual activity outside of marriage is strongly discouraged, and persons engaging in prostitution are punished by hard labor at low pay.

Hatem said that the Chinese experience can serve as a lesson for other countries, including the U.S., which have high rates of VD. "The cause and treatment of venereal diseases are known. They can be eradicated," he said. Regardless of the political or social order, "once you know that, you can find ways to do it."

According to Farber, pregnant women are no longer tested for VD, and protective drops are not put in the eyes of newborns. In the 20 hospitals he visited, "none of the young doctors had ever seen a case of VD. Only the older ones had."

Although great advances in medical care have been made in the last two decades, much remains to be done. "There is a tremendous volume of patients at the clinics, and too few doctors," he says. For example, nearly 500 patients are seen each day at the average dermatology clinic.

"Many physicians in China are behind in their research," says Farber, "but they are conscious of it and want to catch up."

Chinese herbal medicine is still practiced widely and taught in medical school. However, "it is now subjected to closer scrutiny and to scientific discipline to determine its role in the treatment of disease," he says.

In addition, Chinese officials plan to send thousands of their physicians to foreign schools for further training, he says.

STANFORD—The 11th annual Symposium on Renal Disease will be held Friday, Sept. 15, at Stanford University Medical School.

The day-long event, which is sponsored by the Kidney Foundation of Northern California, will provide physicians and other medical personnel with updated information on renal function, and diagnosis and treatment of renal and urinary tract disorders.

Simultaneous sessions will be held for doctors, nurses, technicians, social workers, dieticians and other medical personnel. Lectures will be held in Fairchild Auditorium and in M106 of the medical school.

Among the symposium participants will be Drs. Rex L. Jamison, head of the Division of Nephrology at Stanford; Floyd C. Rector Jr., professor of medicine at the University of California in San Francisco; Norman Kaplan, professor of internal medicine at the University of Texas in Dallas; Fredric L. Coe, professor of medicine at the University of Chicago's Pritzker School of Medicine; Elliot Aronson, professor of psychology at the University of California in Santa Cruz; and Eli A. Friedman, professor of medicine at Downstate Medical Center in Brooklyn, N.Y.

STANFORD—Five young scientists at Stanford University School of Medicine recently have been selected to receive Biomedical Research Support grants for 1978-79.

The funds are provided by a grant from the National Institutes of Health each year "to enhance the effectiveness and efficiency of biomedical and behavioral research" at medical institutions.

The awards are made by a faculty committee chaired by Dr. Eric Shooter, professor of neurobiology.

The grantees, all assistant professors, are Roland Ciaranello, M.D. (psychiatry), S. David Holtzman, M.D. (neurology), Abdul Matin, Ph.D. (medical microbiology), James Rothman, Ph.D. (biochemistry), and Stuart W. Young, M.D. (radiology).

• • •

Ciaranello will study the genetics of the dopamine receptor in the mouse brain. "Dopamine is a substance that transmits nerve impulses from one nerve cell to another," explained Ciaranello. "Target cells within the brain that receive dopamine may play an important role in the pathology of schizophrenia."

Holtzman is studying how the astrocyte uses oxygen and gains energy for growth and other metabolic functions. "The astrocyte is a cell that appears during brain development," said Holtzman. "It contributes to the properties of a mature brain, and may be important in determining the brain's ability to resist toxic or noxious agents."

Matin is studying regulation of membrane processes that occur during energy generation and consumption by microorganisms. "Living cells generate energy by the expulsion of protons through their membranes during respiration," said Matin. "We hope to determine what aspects of membrane permeability are involved in the regulation of proton expulsion."

Rothman is studying how cell membranes are formed. Membranes surrounding the cell and various structures within the cell carry out distinct functions and contain different enzymes, noted Rothman. "We are trying to understand how the correct enzymes are directed to specific membranes during cellular growth and division."

Young is attempting to affect the blood flow to malignant tissue and surrounding normal tissue by the administration of drugs.

"A selective increase in blood flow and delivery of radiographic contrast agents to the malignant tissue should improve the diagnostic precision of computerized tomography scanning," Young noted. Cancer treatment also would be improved if there was more selective delivery of drugs to the tumor.

STANFORD—A Stanford University Medical School researcher has been awarded federal grants totalling over $250,000 to study regulation of enzymes thought to play an important role in human behavior and mental illness.

Dr. Roland Ciaranello of the Department of Psychiatry and Behavioral Sciences has received a three-year grant from the National Institutes of Health to study genetic regulation of enzymes that synthesize catecholamines. Catecholamines are chemical substances that act as neurotransmitters in the brain.

"Changes in enzyme levels are associated with different behavioral states," noted Ciaranello. We have evidence that the factors which provoke these changes are genetically determined."

A two-year grant by the National Science Foundation will support his research on regulation of the hormone, adrenaline, which is important in the way people respond to stress.

"We want to learn how the enzyme that synthesizes adrenaline is turned on and off by steroid hormones," Ciaranello said.

Ciaranello, who received his M.D. degree from Stanford in 1970, is assistant professor of Child Psychiatry and director of the Laboratory of Developmental Neurochemistry.

EDITOR: The following is an announcement of two up-coming conferences on advances in the diagnosis of heart disease September 11-14 at Fairchild Auditorium, Stanford University Medical Center. Press arrangements are being handled by the News Bureau, Room TC 135, Stanford University Medical Center, Stanford, CA 94305. Programs of the conferences are available upon request.

STANFORD—Computerized tomography (CT scanning), measurement of blood flow with ultrasound, and a nuclear "stethoscope" are some of the recent developments in cardiology which will be discussed at Stanford University during two international conferences September 11-14, 1978.

Advances in microelectronics and computerized signal processing have provided physicians with "an increasing range of diagnostic tools and techniques for obtaining quantitative information about the heart and blood vessels in health and disease," say Drs. Donald Harrison and Gene Schmidt of the Stanford division of cardiology, which is hosting the conferences.

The first conference, September 11-12, concerns noninvasive cardiovascular measurements using ultrasound, nuclear scanning and magnetocardiography. It is co-sponsored by the National Aeronautics and Space Administration, and will be followed by the fifth annual conference on computers in cardiology September 12-14.

Some of the topics to be discussed at the two conferences include:

• a "nuclear stethoscope." This device monitors heart function by measuring the radioactivity present in the left ventricle after injection of a radioactive tracer. With the aid of a microprocesser, or small computer, it can measure left ventricle function at rest and during exercise, and after a heart attack, without having to place catheters in the patient's blood vessels and heart chambers.

• computerized tomographic (CT) scanning. Existing CT scanners are too slow to freeze the action of the heart unless scanning is done in synchrony with the heart rhythm. Stanford researchers are working on the technique, which can detect heart attacks in experimental animals.

• blood flow measurement by Doppler ultrasound. The velocity of blood moving through a vessel can be related to changes in the frequency of sound bounced off the vessel. This phenomenon is known as Doppler shift. The non-invasive technique potentially can provide more information about the dynamics of blood flow than catheterization.

• computer enhancement of angiography. Angiography refers to the injection of dye into blood vessels and heart chambers to make them more visible to X-rays. The risks of this procedure can be considerably reduced if the dye is injected through smaller vessels in the arms or legs. Computer signal processing increases the contrast and clarity in angiograms taken with this less invasive technique.

FOR IMMEDIATE RELEASE

STANFORD—

Stanford University Hospital nurses Tuesday, Oct. 31, withdrew their resignations following discussions with administrators to resolve problems surrounding the newborn intensive care nursery.

The nurses said they decided to withdraw their resignations that would have become effective Nov. 7 after hearing details of plans for improvements in space and staffing in the nursery.

Catherine Van Buren, staff nurse on the unit, said a factor in the decision was the "cooperation of the hospital in providing temporary measures for additional space, and better staffing by physicians and nurses."

Renovation is scheduled to begin on Wednesday, Nov. 1 to widen the patient care area. Construction of a new nursery should be underway next year.

Gary Mecklenburg, hospital administrator, said he is pleased with the nurses' action and that the hospital has shared their concerns for improving space and staffing.

"We are confident that the measures in process will provide immediate and long-term resolution of the problems," he said.

STANFORD—Stanford University Hospital nurses and administrators held another round of talks Friday, Oct. 27 and reported progress toward solving some of the problems surrounding the newborn intensive care nursery.

"There was positive discussion, and we feel we have received concrete proposals for action," said Kathy Gesley, staff nurse.

Most of the nurses on the unit had submitted their resignations on Oct. 19, to become effective Nov. 7, protesting insufficient space for providing care, and the need for more intensive coverage by physicians.

"We have been promised 24-hour housekeeping coverage, an additional room, and specific renovation to widen the patient care area immediately," said Gesley.

The nurses have not withdrawn any resignations at this time, but will be meeting on Sunday and Monday to discuss this possibility.

Gary Mecklenburg, hospital administrator, said, "We will be proceeding to implement improvements in the facilities while plans for construction of the new nursery are underway.

"I am confident that the problems will be resolved mutually without reason to curtail patient admissions," he said.

Plans call for tearing down some walls in the unit in order to widen the patient area. This renovation should be underway by Wednesday, Nov. 1. Patients will be cared for in other areas of the nursery while the construction is underway.

Earlier this week the nurses reported progress in their discussions with staff pediatricians. Provisions were made, they said, for more medical coverage at all times in the nursery.

STANFORD—Stanford University School of Medicine should provide incentives so that medical students can graduate in five years or more, according to the curriculum evaluation subcommittee of the Faculty Senate.

Chaired by Dr. Robert A. Chase, the subcommittee will discuss its report before the Medical School's Faculty Senate at 3:30 p.m. Nov. 17 in Room S102 of the Medical School.

"Because students have increasingly opted for a four instead of a five-year curriculum," the report said, "they have not been able to make use of some of the unique characteristics of Stanford."

These include a small student body, high faculty to student ratio and "an extremely talented faculty," the report declared.

Graduating in four years "has also meant that students have had less time to pursue scholarly investigative efforts," said the report.

The medical school should take steps "to reverse these unfortunate trends and to maximize the educational opportunities assuring that all students gain experience in problem solving in the medical sciences," the report recommended.

"The committee supports all efforts to generate incentives for students to spend five or more years matriculated as medical students at Stanford," the document added.

This could be achieved by removing the main disincentive, the extra cost involved.

"The committee strongly endorses a global tuition fee for work at Stanford Medical School toward the M.D. degree, regardless of whether it be achieved over four, five or six year-period," the report said.

In addition, the committee recommended a preceptorship requirement which would culminate in both an oral presentation and written report.

"The committee feels these two proposals would rejuvenate the exciting academic atmosphere and strengthen the relationship of students to faculty" without jeopardizing the present elective curriculum, the report said.

The report said there should be both external and internal evaluation of student competence. Presently Stanford medical students must pass the National Board examination according to the School's requirements for the M.D.

- more - 1

"The committee feels that in addition there should be intramural evaluation of student achievement and learning on a continuous basis . . . to determine the extent to which the student has met the educational objectives established by the faculty." said the report.

In 1959 the Stanford medical curriculum was completely rebuilt to improve the training of future physicians. It spread their studies over five years instead of four, taught them principles instead of mastery of specific detail and emphasized the unity of biology and basic medical sciences.

In 1968 that curriculum was prematurely changed, according to critics, on the basis of a few crucial decisions.

These included the development and sale of the four-year track to incoming students, the decision to charge five-year students 25 percent more tuition than four-year students, the arguments for federal capitation grants to increase class size, and the "false idea" that a small faculty would massively increase its teaching and administrative functions.

The committee endorsed the objectives of the 1959 curriculum because "it represents ideals which this medical school should continue to espouse."

The committee said: "In the light of experience of almost two decades, it is apparent that strategies to meet these objectives must be tailored to realistic expectations placed on a Medical School faculty and students."

The committee said that Stanford's most important aims should remain

. the encouragement of student individualty.

. the fostering of a graduate approach to medical education.

. encouragement of interest towards an academic career in medicine.

. training of physicians who in the course of their career will continue to adhere to the scientific method.

. the promotion of student awareness of the place of medicine in society.

"The School provides the type of environment in which its faculty members and students can fulfill what they consider to be an imperative obligation to enlarge their field of knowledge." the committee said.

STANFORD—"Good Health Habits: A Way of Life" will be the topic of the second lecture in the Progress in Medicine series of the Stanford University School of Medicine, to be held Wednesday, Nov. 1.

The lecture is open to the public at no charge, and will begin at 7:30 p.m. in the Sherman Fairchild Auditorium.

Dr. Ralph S. Paffenbarger, Jr., professor and head of the division of epidemiology, will discuss health habits worth cultivating. His research has focused on long-term studies of disease patterns, particularly the relationship of vigorous exercise and heart disease.

His most recent study of Harvard alumni received wide public attention. That work showed that there were fewer heart attacks among those who participated regularly in strenuous sports activities than among less active persons.

Paffenbarger joined the new division of epidemiology at Stanford last year. He formerly served as adjunct professor of epidemiology at the University of California School of Public Health in Berkeley. He has taught at Harvard, and was medical director of the U.S. Public Health Service for 21 years.

Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine and by the members of the Medical Center Council.

Future speakers will discuss "Early Disease Detection: Designing a Personal Screening Program," by Dr. David M. Eddy on Nov. 8, and "How to Choose and When to See the Doctor" by a panel of physicians on Nov. 15.

STANFORD—Stanford University School of Medicine ranks seventh in the nation in its ability to attract minority students, according to an institutional profile report just released by the Association of American Medical Colleges.

The report, which covers the 1976-77 academic year, shows that non-Caucasian students in the medical school constituted 25 percent of the student body.

This year 20 percent of the students in the entering classes represent minorities--black, Chicano, and native American.

These percentages are similar to those of past entering classes, according to the office of student affairs.

Earlier this month the Medical School faculty senate overwhelmingly affirmed its satisfaction with the current level of minority admissions and the school's continuing commitment to minority admissions under the Bakke guidelines.

The senate backed that commitment by enlarging the Admissions Committee to include more minority representatives, and by creating a special panel to engage in active recruiting of qualified minority applicants.

Stanford also ranked fourth among the nation's medical schools that are dependent on federal support, and 41st in the degree to which the school depends on revenues from faculty medical practice.

The school ranked high on such areas as student/faculty ratios, expenditures of faculty support for research, and emphasis in research.

But it scored low on the list in terms of the number of faculty who hold tenured appointments, and the extent to which it trains resident physicians in primary care.

The institutional profile report is generated annually by the Association of American Medical Colleges. It highlights rankings of each school in comparison to others. The report covers 114 medical schools, but they are not identified by name.

STANFORD—SUMEX, the national computer network based at Stanford University, recently received $500,000 for each of the next three years from the National Institutes of Health (NIH) to continue studying the applications of artificial intelligence to medicine.

Artificial intelligence refers to the emerging capabilities of computers to reason symbolically with the use of knowledge.

The renewed funding comes during a time of change for SUMEX (Stanford University Medical EXperimental computer), which was established by the NIH in 1973.

A co-founder, Professor Joshua Lederberg, recently left Stanford to take up the presidency of Rockefeller University in New York. His colleague, Professor Edward Feigenbaum, will take over administration of the computer system.

This also is a time of rapid change in computer technology. "The computing capacity of a machine which 10-15 years ago cost a million dollars today can be bought for $75,000, and within 10 years, it will be a $25 vest pocket calculator," says Lederberg.

Computer facilities such as SUMEX are currently quite costly, but advances in technololgy, and sharing the computer between several investigators, is "significantly reducing the cost per project," says SUMEX director Thomas Rindfleisch.

The advantage of a large, time-shared system like SUMEX is that it permits rapid interactions and cooperation between many research groups, says Rindfleisch. Currently, SUMEX provides the hardware for 15 problem solving projects nationwide, in fields ranging from organic chemistry to medical diagnosis.

Fifteen years ago, explorations in artificial intelligence were limited to mathematical exercises and games of chess. In the mid-1960's, researchers began to apply the computer's "brain" to solving tough problems in chemistry and biology.

One problem explored by Lederberg and Feigenbaum was the determination of molecular structures from mass spectrometry data in organic chemistry.

With the help of chemistry professor Carl Djerassi, who supplied his expertise about the behavior of organic molecules, and computer scientist Bruce Buchanan, they constructed a computer program which could generate unerringly all possible structures of a molecule based on the knowledge and spectrometry data supplied to it.

The program, called DENDRAL, has become an important tool for generating and checking structure proofs, a chemist's "intelligent assistant."

"Humans find the single answer well, but they can't give a guarantee that there are no other possibilities," says Buchanan. "The computer can."

DENDRAL's success stimulated investigations in other areas of science, notably medicine. MYCIN, an expert program in infectious diseases, emerged from the concern of Dr. Stanley Cohen of Stanford and Dr. Stanton Axline, now at the University of Arizona, about the indiscriminate use of antibiotics.

-more-

Employing the expertise in bacterial infections and antibiotics of the two physicians, computer scientists Buchanan and Edward Shortliffe, who later earned his medical doctorate at Stanford, developed a program which could make recommendations about diagnosis and treatment in a straight forward, easily understood manner.

"We had to design a program which could communicate in simple English, which could understand questions posed by physicians, and could explain its decisions in a way they can understand," says Shortliffe.

Programs like MYCIN are often regarded by physicians with skepticism, some of whom feel the machine is invading their relationship with patients.

"It was important for us to respond to these feelings," says Shortliffe. "We're not trying to replace the use of reason by physicians, but simply add to the available tools and procedures which make their practices more effective.

"I do not see physicians choosing the computer over the human expert if they are side by side," he says. "But the computer is more accessible. It can be reached in the middle of the night. A portable terminal can be tied into a central facility from remote rural areas, submarines, even from space."

Other projects began at Stanford, including MOLGEN, a program which assists the design of experiments and data analysis in molecular gemetics, and PUFF, a respiratory disease specialist developed by researchers at Stanford and San Francisco's Pacific Medical Center.

By the early 1970s, other groups throughout the country had established research programs in artificial intelligence. The need for a larger facility at Stanford, and the high cost of duplicating computer programs for use at other locations, led the Stanford group to propose the formation of a national research resource. That proposal was granted by the NIH in 1973.

Today, the SUMEX computer aids research at other centers, such as the Rutgers University glaucoma consultation system, and INTERNIST, an expert in internal medicine at the University of Pittsburgh.

In addition to its usefulness in problem-solving activities, artificial intelligence is improving understanding about the way knowledge can be organized. "Our work has made us realize the huge knowledge base people use in solving apparently simple problems," says Thomas Rindfleisch. "Our main job has been learning how to acquire and represent that knowledge."

"We've found out that a great deal of expertise is based on good guesses and plausible reasoning," says Feigenbaum.

"In the long run, the important result of our work may be the ability to explain a private body of knowledge so it can be taught, discussed, and built into consensus."

Bruce Buchanan puts it more simply: "If we can capture the knowledge of a thin slice of molecular genetics that Lederberg, for example, has in his head, we will have done a big service for students now and in the future."

FOR IMMEDIATE RELEASE
STANFORD—

Plans are under way to establish a Life Support Training Center for the teaching of cardiac life-support techniques for doctors, nurses, and the general public at Stanford University Hospital.

The Center, which will be the first of its kind in California, will help meet the growing need for training in cardiopulmonary resuscitation (CPR) and advanced life-support systems, Dr. Michael Eliastam, director of emergency Services at Stanford told a group of mid-Peninsula service club members Thursday (Oct. 26).

In addition to CPR training equipment, Eliastam says the facility will contain the required sophisticated electronic teaching equipment used in the training of advanced life support. The Center will be housed in Stanford Hospital's new wing.

"The need for this training center is clear," Eliastam explained. "Both the American Red cross and the American heart Association are unable to keep up with the demand for training among the lay public and professional health groups.

"This (Center) is truly a university-community combined venture, and the Center will be available not only to Stanford's medical community, but also to other physicians and nurses and interested groups in the community," Eliastam said.

Instruction will be provided by faculty members at Stanford Medical School, including physicians in emergency medicine, anesthesia, and cardiology. Instructors from the lay community also will be major instructors in the CPR program, Eliastam said.

"Life-support training will be especially helpful for physicians and nurses since it will provide them with a thorough, updated review of their knowledge and skills of resuscitation techniques."

Eliastam said the Stanford Center will also be available to the Red Cross and American Heart Association as a training site for lay people.

Advanced cardiac life-support techniques involve the use of drugs and sophisticated technology, as well as basic life-support procedures.

These procedures or techniques may often mean the difference between life and death for a heart-attack victim, or between disability and good health.

Stanford officials estimate renovations in the Hospital wing to accommodate the new Center will cost about $17,000.

STANFORD—The United States is falling behind other countries in terms of the rate at which scientific work is done and in the general level of competence of researchers, a committee of scientists warned Wednesday, October 25.

In a report released in Washington, the committee blamed part of the problem on the accelerating decline in the quantity and development of scientific instruments available for research in the U.S., particularly in the chemical, biological and medical sciences.

It called for development of regional facilities and "wider sharing technology resources."

The committee, headed by Oleg Jardetzky, professor of pharmacology at Stanford University School of Medicine, cited studies which show that:

. the quality of scientific equipment at research centers has deteriorated.

. the number of top-notch research centers is declining.

. researchers are tending to avoid risky or more innovative projects because of the tight money environment.

. research opportunities for young scientists have diminished.

. training of young scientists is deteriorating, because generally available technology is rapidly becoming obsolete.

"Many young people are not now being properly trained because many universities have no access to first-rate modern instruments," said Jardetzky.

In addition, "a number of practical discoveries which can be made with modern instrumentation is likely to be made somewhere else, and the potential for commercial exploitation is likely to be lost from this country," he warned.

The committee report states that funding for instrumentation by the federal government has remained at a constant level since 1967, and that "an adequate net increase in funds from Congress to remedy the instrumentation problem is difficult to expect in the present economic climate."

Given the lack of funds, a reversal of the decline in the quality of scientific equipment is possible only through "wider sharing of technology resources."

"We do not have enough money, nor will we have enough in the foreseeable future to buy an instrument for every scientist who can justify a research need for one," said Jardetzky.

-more-

2-2-2 The committee made its report to Frank Press, director of the Office of Science and Technology Policy; Richard Atkinson, director of the National Science Foundation; Philip Handler, president of the National Academy of Sciences; William Raub, associate director of the National Institutes of Health, and representatives of the Office of Management and Budget.

The committee's recommendations have been sent to several congressional leaders, said Jardetzky, and they will appear as an editorial in the October 27 issue of Science magazine.

Jardetzky said the national ad hoc committee was formed following a recent meeting of directors of several regional instrumentation facilities "to examine the situation and seek some practical solutions."

Committee members included E.R. Blout, Harvard University; D.M. Grant, University of Utah; W.D. Phillips, Washington University; and K.R. Porter, University of Colorado.

The committee specifically recommended that the budgets of agencies responsible for funding regional and shared facilities be increased or redistributed.

In addition to calling for a commitment by the federal government to greater regionalization, Jardetzky said the committee may "seek a Congressional mandate for increasing or redistributing the budgets of these agencies."

"Neither the NSF nor the NIH are currently set up to fund many regional facilities," he said.

The NSF's division of chemical instrumentation has recently announced a new program to establish regional laboratories but funding has as yet been secured for only one year. No parallel program for biological instrumentation exists.

"The bulk of funding goes through categorical research grants to specific individuals for specific research projects," said Jardetzky. This only encourages scientists to seek expensive equipment for their own use rather than share it with other research groups, he said.

Sciences such as biology and chemistry did not have funding problems 20 years ago, when government grants were more plentiful, and researchers worked on an individual basis with relatively simple equipment, said Jardetzky.

But new technology, which permits a more sophisticated approach in science, is often tremendously expensive.

Instruments such electron microscopes, nuclear magnetic resonance (NMR) spectrometers, laser and X-ray installations usually over $100,000 per item, said Jardetzky.

Jardetzky, director of the Stanford Magnetic Resonance Laboratory, helped design the world's first 360 MegaHertz NMR spectrometer in 1974. That instrument enables researchers to examine the magnetic properties of atoms in a molecule, and provides information about their spatial relationships and movements.

The Stanford machine is shared with scientists from other institutions, and to date, only two other machines have been made publicly available in the country.

STANFORD—Nurses in the newborn intensive care unit at Stanford University Hospital have reported progress in their discussions with staff pediatricians, following a meeting Monday, Oct. 23.

"The medical staff has made a positive response to our requests," said Rose Anne Petersen, unit staff nurse. "It has shown a good faith effort to solve the problems," she said.

Thirty-four nurses in that unit had submitted their resignations last week, to be effective Nov. 7, protesting insufficient facilities and staffing.

No resignations have been withdrawn at this time. "Individual staff members will make any decisions about whether they will withdraw resignations and when," she said.

Dr. Irving Schulman, chairman of pediatrics, affirmed at the meeting with the nurses that there will be more medical coverage, said Petersen, with a senior physician available at all times to the nursery. Previously, the physician coverage was shared with other nursing units.

In addition, provisions have been made for senior staff to plan an intensive orientation program for all new resident physicians entering the nursery.

Representatives of the nurses will continue to meet with hospital administrators in the next few days concerning nursing staffing and facilities.

The nurses had cited insufficient space for providing care in the specialty unit, and the need for more registered nurses and medical staff.

According to Gary Mecklenburg, hospital administrator, plans for a new intensive care nursery are underway to relieve the currently overburdened facilities.

Mecklenburg also said that recruitment of specialized nurses for the unit is continuing.

STANFORD—Treating patients in two of Stanford University hospital's specialized day care centers has cut the costs of their care in half, according to hospital officials.

As a result, the services will be covered by Medicare, the officials said.

The cost savings apply to cancer patients receiving long-term chemotherapy in the new Oncology Day Care Center and severe psoriasis patients in the Dermatology Day Care Center.

Only those patients who formerly would have been admitted to the hospital for their long-term drug treatments are covered by the Medicare benefit.

In a recent letter to the hospital, Blue Cross officials wrote "...we have concluded that the costs (for day care patients) are approximately one-half of other patients receiving oncology services. We are pleased to inform you that the Oncology Day Care Center is approved for Medicare purposes."

The Medicare approval for the oncology center is similar to that received last year for the Dermatology Day Care Center.

According to John Kneepkens, clinic manager, oncology patients were admitted to the hospital for at least two days, at a basic room rate of $187 per day. That cost, he says, has been reduced by half because of the new day care facilities which now provide the same services, including intensive nursing care.

The cost-cutting efforts were successful last year in persuading Blue Cross, Medicare, Medi-Cal, and several other insurance companies to accept day care as a benefit for dermatology patients.

Kneepkens said he is hopeful that other carriers will also accept the same billing procedure for oncology center patients. He said he will be working with patients and their insurance carriers to achieve this.

"It is a serious attempt to reduce medical care costs," says Kneepkens. "the goal is to provide inpatient services on an outpatient basis at the lowest possible cost consistent with good medical practice."

Oncology patients arrive in the morning and receive chemotherapy over a six to eight hour period. During this time they require close supervision, with monitoring of vital signs and intensive nursing. These patients may return once every week for an average of six months.

Formerly they were seen in the oncology out-patient clinic, then were admitted to the hospital for more than two days a week.

Besides the reduced cost, patients now have less administrative forms to deal with, such as registration and insurance. They also have a pleasant home-like atmosphere, a familiar staff for each visit, and modern comfortable treatment facilities.

The center operates both as a clinic and as a day care center, accommodating normal clinic patients as well as those requiring long-term infusion of chemotherapy drugs.

In the Dermatology Day Care Center, patients who previously would have been hospitalized now report to the center in the morning five days a week. Their therapy sessions last seven or eight hours, enabling them to return home in the late afternoon.

The average treatment in the dermatology center lasts about 10 days. Costs, says Kneepkens, are about half what they had been for hospital care before the center opened.

Most of the patients have 50 to 75 percent of their bodies involved with psoriasis, with lesions too extensive to treat at home. The center also meets the needs of those who cannot afford to spend time away from their families or jobs for hospital treatment.

STANFORD—Children who are victims of child abuse are likely to grow up to become abusive parents, a group of Stanford medical students and medical professionals learned recently at a one day workshop on child abuse held at Stanford University Medical School.

"Child abuse is a language of pain," a panelist told the group. "Many abusive parents are desperate for help themselves, and they strike out to express their pain."

The workshop was organized by a group of medical students seeking exposure to the social, legal and medical implications of child abuse.

Sponsored by the department of pediatrics, the workshop featured films and a panel discussion with a group of experts. They included Dr. Frederick Lloyd, associate clinical professor of pediatrics; Rose Grobstein, chief of pediatric social services at Stanford Hospital; Ken Kondo, juvenile officer from the Palo Alto Police Department; Betty Lin, social worker from the protective services agency of Santa Clara County; Judge Eugene Premo from the California superior court; and a parent of an abused child.

A diagnosis of child abuse is a "discouraging and emotionally laden" one for physicians, said Lloyd, and "reluctance to make the diagnosis is a stumbling block" to cure.

"But this is an area of medicine where preventive measures are clearly effective and the results of treatment can be very gratifying," Lloyd told the students.

Although a dramatic rise in child abuse has been observed recently, Lloyd attributes this to greater awareness of the problem and increased reporting of incidents.

"We have been abusive as long as we've been a species," he said.

Treatment depends on the interaction of many people and institutions, including hospitals, social service agencies, the courts and the family, the panelists agreed.

Families of abused children are often isolated, Grobstein explained, and 85 percent of abusive parents cannot identify a person they can turn to in times of stress.

Although divorced or single parents are more at risk, child abusers occur in all socioeconomic groups, in all age brackets, and generally cut across all walks of life, Grobstein said.

"I am uncomfortable with the idea of 'we' and 'they'," Lin told the students "because all of us are potential child abusers."

Usually, a crisis triggers the abuse, and one parent is the abuser while the other parent, either passively or actively, goes along with the act, said Grobstein.

The parent who spends most time with the child is more likely to be the abuser, and mothers are four times more likely than fathers to mistreat children, according to Grobstein.

Abused children are often seen as "different" by the parents, said Grobstein. Children who are smart, retarded, hyperactive, children with birth defects or those born prematurely, are more likely to suffer abuse, she said.

- more -

Ignorance of normal stages of development or unrealistic expectations of children may also lead to abuse, Grobstein added.

"A child who cries frequently, an infant who soils his diapers, or a two year old who has trouble making his own breakfast," are all examples of children Grobstein has seen who have been abused by parents with unrealistic expectations.

But those trying to help must not respond angrily to parents, Grobstein warned. More effective treatment is to help parents find relief from the stressful situation which led to abuse, she said.

This often requires counseling from a social worker like Lin, who said "my job is to teach my clients how to gain self-respect and listen to their own needs."

"We want to help them find some joy in life," Grobstein added.

In Santa Clara county, doctors are legally required to report any suspicion of child abuse to the protective services agency or the probation department, Premo explained.

Kondo outlined the role of the police department in child abuse problems. When the police receive a report of a suspected case, Kondo visits the home with a co-worker from the protective services agency. Together, they make a determination of the immediate family situation and acquire evidence which may be used at a later time.

With the aid of social workers, many cases are resolved informally at this stage.

If the case proceeds to a formal court hearing, the child could be placed temporarily in a foster home or a children's shelter in an extreme case, said Premo.

At the hearing, both the child and the parent have a right to legal counsel, and the final decision depends on "a preponderance of evidence," Premo explained. If a child is finally removed from home, a plan for his welfare must be submitted.

Juvenile cases have highest priority in the judicial system, with a maximum period of 15 days between initial report and court hearing, added Judge Premo, who previously served on the juvenile court for three years.

The panelists stressed their common goal of helping parents and attempting to reunite the family.

"The best place for a child is in the family, if parents can be helped not to abuse," Grobstein said.

(ADVANCE) FOR MONDAY, OCTOBER 23, 1978
City Desks: Release date set by American Cancer Society

STANFORD—Stanford University Hospital will be one of five research institutions selected to carry out clinical trials to test the possible anti-tumor effect of interferon.

The names of institutions were released Monday, Oct. 23, by the American Cancer Society which has allocated up to $2 million toward purchase of the material for use in the tests.

Interferon is a natural body substance which has been shown to reduce the size of tumors in animal experiments as well as in a few scattered applications to human cancer patients. "Its ultimate usefulness against cancer has yet to be proved," an ACS statement cautioned.

The Society also named six kinds of cancer against which the interferon will be tested. Each kind will be studied by at least two institutions.

According to Dr. Thomas A. Merigan, professor and head of the Division of Infectious Diseases at Stanford, the clinical trials in the Stanford hospital will concentrate on non-Hodgkins lymphoma.

The work will be carried out by the Oncology Division headed by Dr. Saul A. Rosenberg, professor of medicine and radiology, in collaboration with the Merigan group noted for its work in interferon research.

The ACS has stressed that because of the scarcity and extreme high cost of interferon the research will be limited to 25 patients for each type of cancer, a total of 150 patients.

The University of Texas M.D. Anderson Hospital and Tumor Institute of Houston, Texas, will work on five of the cancer types—breast cancer, melanoma, multiple myeloma, squamous cell cancer of the lung, and non-Hodgkins lymphoma, according to the ACS statement.

Sloan-Kettering Institute for Cancer Research in New York City will work with four types of cancer—non-Hodgkins lymphoma, melanoma, squamous cell cancer of the lung, and cancer of the bladder.

Roswell Park Memorial Institute in Buffalo, New York, will study breast, melanoma and bladder cancers, and the Columbia University College of Physicians and Surgeons in New York City will conduct trials on patients with multiple myeloma.

Dr. Frank J. Rauscher, Jr., ACS senior vice president for research, has issued a note of caution against undue optimism about research results.

"Speculation which raises high hopes because of the Society's unusually large financial commitment is premature,"Rauscher said. "Interferon needs to be checked out because its value has not yet been proved."

Rauscher said the Society was concerned about hundreds of cancer patients and their families who have volunteered to participate in the clinical tests since August when ACS announced its intention to fund the project.

- more -

"Unfortunately, there is absolutely no way that this can be arranged, either by the Society or the participating institutions,"he said. "The number of patients who will be studied is small. Their selection by the institutions will follow objective research protocols which exclude bias of any kind."

The ACS said the first shipments of interferon for use in the clinical tests have been made, and that initial studies should be underway in at least some of the participating institutions by mid-November.

However, because of the limited availability of the material, the project may not become fully operative for another 12 to 18 months.

The material is being imported from Finland, which at this time is the world's primary source of supply.

Interferon, first identified in 1957 by Alick Isaacs of Great Britain and Jean Lindenmann of Switzerland, is extracted from white blood cells. When produced by cells infected by a virus, it appears to protect neighboring cells from infection by the same virus.

First clinical studies were conducted in Sweden. In addition to the American study now being launched, clinical testing also is underway or in planning stages in Great Britain, France, Germany, Austria and Japan.

At Stanford, interferon has been used successfully by Dr. Merigan and his associates to prevent in cancer patients the spread of herpes zoster, a virus which causes chicken pox and shingles. Such a virus infection is more frequent in cancer patients because their immune responses have been reduced by chemotherapy and radiation treatment.

Interferon has not been synthesized nor has the gene for its production been isolated. Work is in progress in both areas.

STANFORD—Thirty-two nurses who work in the newborn intensive care unit of Stanford University Hospital have submitted their resignations, to be effective Nov. 7. They have protested insufficient facilities and staffing on the unit.

Hospital administrator Gary A. Mecklenburg said the hospital shares the nurses' concerns, and "we are hopeful we can provide additional support to persuade them to reconsider their action."

The nurses' action came Thursday, Oct. 19, and hospital administrators, medical staff members, and nursing department representatives are now meeting to resolve the problems.

The nurses cited insufficient space for providing care in the specialty unit, and the need for more registered nurses on the unit as well as more intensive coverage by physicians.

Catherine Van Buren, staff nurse on the unit, said the major issue is inadequate medical staff support. She said space and staff have been inadequate for years.

She compared the unit to other intensive care units in the hospital which also have a similar number of beds but a greater number of nursing staff.

"The current facilities are overburdened and require replacement," says Mecklenburg.

"We are now in the final design process with architects for a new, more spacious intensive care nursery. Initial plans for the new unit, submitted this Fall, had to be redesigned, and we are now awaiting final approval by state licensing agencies. Construction should be underway early next year."

Interim steps to provide space relief for the staff are underway, such as providing conference rooms and additional storage space, he says.

Recruitment of specialized nurses for the unit is continuing, he says. Many recently hired nurses are still in orientation, but will be on the unit soon.

The nurses also said the number of physicians on the unit is inadequate.

According to Dr. Irving Schulman, chairman of Pediatrics, three fulltime faculty neonatologists, three junior-level neonatologists, and four fulltime resident physicians, all MDs, are assigned to the unit. According to Schulman, the physician staffing patterns are being reevaluated in an attempt to provide still more physician involvement.

Stanford is recognized as a leader in the field of intensive care for infants. The unit has facilities for 21 intensive care bassinets, and is usually at full occupancy. A total of 72 nurses normally staff the unit.

STANFORD—An appeal of the dismissal of several causes of action in a damage suit against Stanford University Hospital has been filed by the two plaintiffs in the case.

In their appeal, current hospital employee Conroe C.McGee and former employee Frank Petta, have asked Judge Marilyn Pestarino Zecher of Santa Clara County Superior Court to rescind her ruling of last summer.

In that decision Judge Zecher dismissed three of four causes of action in the case, which involves claims of job harassment and demotion. However, no ruling was made on a fourth cause involving Petta.

In addition to the hospital and 20 John Does, three persons were named as defendants, including Jim McNally, former director of the hospital's Facilities Department, chief engineer William Ferguson and general foreman David Dominguez.

The court's ruling had dismissed all action against both Ferguson and Dominguez.

McGee and Petta had each sought $100,000 in general damages and $500,000 in punitive damages, or $1.2 million total.

STANFORD—Professor Paul Berg of Stanford University yesterday, October 18, revealed his attempts to transplant functioning genes from one mammalian species to another.

The discussion of his work was in response to reporters' questions preceding an address on genetic manipulation to the clinical congress of the American College of Surgeons.

He did not intend to make public the details of his work which is being submitted for publication in a scientific journal.

But because of the premature announcement in the newspapers he has agreed to make the following statement.

Berg and his associates, Richard Mulligan and Bruce Howard, spliced a segment of DNA that codes for the beta chain of rabbit hemoglobin into SV40 virus DNA.

African green monkey cells were then infected with the hybrid virus DNA to permit the newly incorporated gene segments to be amplified, said Berg.

The Stanford researchers found that rabbit beta hemoglobin was synthesized in these infected cells.

This is the first instance in which a mammalian gene of one species has been made to function in another mammalian cell species using recombinant DNA techniques, said Berg.

In his earlier speech before the American College of Surgeons, Berg spoke about the background and recent developments in the recombinant DNA field.

Berg said these kinds of experiments have "opened the way to understanding the molecular organization of chromosomes and the mechanisms of gene expression in health and disease."

This understanding may shed light on the genetic basis of many diseases such as hemoglobin disorders, diabetes, etc., and may provide the basis for more rational therapies.

"It is quite clear that the isolation of genes and the ability to manipulate them puts us at the threshold of a new form of medicine, the treatment of crippling genetic diseases through replacement of defective genes by their normal counterparts," said Berg.

"There is no doubt that the development and introduction of the recombinant DNA techniques has opened a new era of scientific discovery, one that promises to influence our future in myriad ways.

"Yet this great leap forward has revealed, or perhaps created, an underlying apprehension about probing 'the nature of life itself.'"

Berg, Willson professor of biochemistry at Stanford, was one of the first scientists to raise questions about the potential dangers of recombinant DNA research in 1971.

Berg said the concern about these experiments expressed by him and other scientists "triggered a scientific, public and governmental debate which has raged for the past three years. It is still not ended." However, "I and my colleagues meant to raise for scrutiny and analysis the issue of whether recombinant DNA experiments are safe," he said.

"I and most scientists believe that our initial concerns were premature and unwarranted," he said.

Presently, guidelines established by the National Institutes of Health in 1976 require that recombinant DNA research follow strict procedures of physical and biological containment.

Berg's experiments, for instance, are conducted in a carefully controlled laboratory environment designated P3, using SV40.

"While a case can be made that some vigilance in performing those experiments is prudent, the bulk of research in this field should be relieved of the bureaucratic restraints that now stifle it," said Berg.

STANFORD—The Northern California Infant Medical Dispatch Center has received $83,000 from the State of California to continue emergency transport of seriously ill infants to intensive care nurseries.

The center, based at Stanford University Hospital, coordinates the intensive care resources of 10 hospitals from the Oregon border to the Tehachipi Mountains. A similar center, at the University of Southern California, serves the southern portion of the state.

The money is part of $300,000 given to support the state-wide program of emergency infant transport for the year beginning July 1, 1978.

The Southern California center will receive $100,000, and the remainder will be given to the State Department of Health Services to cover the administrative and evaluation costs of the program, according to Dr. Alvin Hackel, director of the Northern California center.

"We feel very fortunate to have this support in light of the financial problems brought about by Proposition 13," said Hackel, also associate professor of clinical anesthesia and pediatrics at Stanford University School of Medicine.

Funding of the program by the State expired June 30 and was not renewed pending examination of the impact of Proposition 13 on the State budget.

During this period, the March of Dimes Foundation gave $20,000 to support the Northern California center. That money will now be returned to the Foundation, said Hackel.

"We deeply appreciate these emergency contingency funds, which allowed us to continue the program until the necessary legislation was passed," he said.

During the next year, the transport program will be evaluated by the State Legislative Analyst for its effectiveness in improving the outcome of babies who require transport to intensive care nurseries, said Hackel.

"In the past, up to two hours have been spent just finding an intensive care nursery with an available bed for these babies," he said. "We feel this extra time compromised the ultimate outcome of these patients."

In comparison, the dispatch centers have reduced the search for empty beds to a matter of minutes, by coordinating intensive care nurseries.

The results of the evaluation will be forwarded to the State Legislature and taken into consideration when the funding of the program comes up for renewal next July, said Hackel.

Also this year, a computerized bed locator system which keeps track of available beds automatically, will be added to the program. Presently, the center staff telephones hospitals with intensive care beds every eight hours, or more often in case of emergencies.

"This system will be the first of its kind in the U.S.," said Hackel, "and has evoked considerable interest in other states."

STANFORD—In Poland, a doctor's career is not as prestigious as in the United States, and doctors may earn one third the salary of bus drivers, says a Stanford physician who recently returned with observations on many aspects of social medicine in Poland.

Dr. Iris Litt, associate professor of pediatrics and director of adolescent medicine at Stanford Hospital, was one of nine doctors in a U.S. delegation of pediatrics specialists who visited Poland in September.

The delegation's visit was part of a six year exchange program between the two countries to explore issues in medical education and manpower.

The trip was sponsored by the international division of the department of HEW.

The delegation's Polish hosts were from the medical academies in the cities of Lublin and Cracow.

Polish students graduating from high school ranked their career choices, and engineering came out on top while physicians were 16th on a list of 30, Litt learned.

Presently, 90 percent of Poland's physicians are women, but in an effort to recruit more men, admissions committees now tack on ten extra points to any man's score.

One woman pediatrician stated, "the man must make the important decisions," in explaining to Litt why a man chaired the pediatrics department at her medical academy, despite figures indicating that 98 percent of Polish pediatricians are women.

The six year training program for doctors includes traditional medical courses, Litt's group learned, as well as training in social medicine, ethics, health care delivery, school health and occupational health.

In each province, three seperate systems provide health care, each with its own set of medical records:

- ambulatory care is delivered through rural health stations in the countryside, primary care centers in towns, hospital outpatient departments, and polyclinics where specialists may be consulted
- school health systems
- emergency hospitals, which handle all medical problems after hours

Litt feels that the lack of a unified system and the duplication of medical records are two obstacles to efficient health care delivery in Poland.

- more -

Government physicians work seven hours per day, five days per week, and five hours on Saturday. After hours, they may work in private practice, but have no access to government facilities.

The group learned that approximately 20 percent of the population still consults a private physician.

Continuity of care is a strong point of health care delivery in Poland, according to Litt. Individuals continue to see the same physician, even though not on a private basis. The system also permits home visits, and dental care is provided.

Continuing medical education for physicians is emphasized. An increase of salary is guaranteed to those who participate for two weeks each year.

A shortage of physicians in the countryside has prompted the government to take action, including favoring rural candidates for medical school, and offering cars and houses as incentives to lure doctors into the countryside.

When Litt and her colleagues exchanged information, she learned that suicide attempts are common among Polish teenagers, as they are here.

Drug abuse occurs with cleaning fluids, other inhalants and alcohol, while opiates are not a problem, as they are in the U.S..

Litt's colleagues told her there are no rapes, no child abuse, and teen pregnancies are so rare as to be an insignificant social or medical problem.

Although abortions are available, Litt was unable to obtain information about them and she observed anti-abortion posters in numerous Catholic churches which she visited.

Birth control pills are available but the rhythm method of contraception is encouraged, and IUD's and diaphragms are seldom used, the group was informed.

Conditions in the hospitals Litt visited varied from bleak and crowded to modern and cheerful. One obstetrical hospital was particularly dreary, Litt reports, and she was dismayed by the lack of attention to issues such as maternal-infant bonding and breast feeding.

However, Litt learned that under the Polish system of health care, mothers receive four months paid leave following delivery, and two years unpaid leave beyond that, with their same position guaranteed upon return.

STANFORD—A new series of four public lectures on "You and Your Health: Options for the Medical Consumer" will begin Wednesday, Oct. 25 at the Stanford University School of Medicine.

The weekly presentations will be held at 7:30 p.m. in the Sherman Fairchild Auditorium. They are free of charge.

"Taking Care of Yourself: A Strategy for Health" will be the subject of the first lecture, presented by Dr. James F. Fries, associate professor of medicine, Division of Immunology.

Fries is coauthor of the popular consumer's guide to medical care, *Take Care of Yourself,* and a similar book on pediatric care, *Take Care of Your Child.*

He is national director of the American Rheumatism Association Medical Information System, and has been involved in medical decision analysis. He will discuss ways an individual may assume personal responsibility for health, monitoring important conditions, and seeking medical advice when appropriate.

Other lectures are:

NOVEMBER 1: "Good Health Habits: A Way of Life," by Dr. Ralph S. Paffenbarger, Jr., professor and head, division of epidemiology, Department of Family, Community and Preventive Medicine. Dr. Paffenbarger will suggest some habits worth cultivating based on his long-term studies of disease patterns. His research has focused on the relation of vigorous exercise and heart disease, particularly in former college students, and the causes of certain types of cancer.

NOVEMBER 8: "Early Disease Detection: Designing a personal Screening Program," by Dr. David M. Eddy, associate professor, Departments of Engineering Economic Systems and Family, Community and Preventive Medicine. Eddy will discuss annual physical exams, screening tests for cancer and other health maintenance topics.

NOVEMBER 15: "How to Choose and When to See the Doctor," presenting a panel of physicians who will suggest guidelines for selecting a doctor and outline some conditions that call for medical consultation. Panel members include Dr. William C. Fowkes, Jr., associate professor of clinical medicine and head of the division of family medicine; Dr. Keith I. Marton, assistant professor medicine; and Dr. Harold C. Sox, Jr., assistant professor of medicine and head of the division of general internal medicine.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine and by the members of the Medical Center Council.

STANFORD—A distinguished panel will discuss "Legal and Moral Aspects of Health Care: Informed Consent" in a free public session Wednesday, Oct. 18, at Stanford.

The session is being sponsored by the Stanford Workshops on Political and Social Issues (SWOPSI) and the Stanford Medical Students Association. It will be held from 7:30 to 9:30 p.m. in Room 112 of the Center for Educational Research at Stanford (adjacent to the law school).

Panelists include Sheryl Brown of the Coalition for Medical Rights for Women; Dr. Roy Cohn, Chidester Professor (emeritus) of Surgery at Stanford; Dr. Halsted Holman, Guggenheim Professor of Medicine at Stanford; Dr. Andrew Jamiton, Health Policy Program at the University of California in San Francisco; and John Levin, lawyer and chairman of the Human Subject Review Committee of the Northern California Cancer Group. Moderator will be Jinnet Fowles, a Ph.D. candidate for Communication Research at Stanford.

FOR IMMEDIATE RELEASE

STANFORD—

Legal action to ensure continued access for community physicians to Stanford University Hospital's clinical services will be taken if necessary, according to a newly formed group of private practice physicians.

"We will exhaust every other means before we go to court, but we also will not negotiate to death," said Dr. Paul Cooney, chairman of the Community Physicians for Patient Care, to the nearly 150 members of the group attending its first general meeting Thursday night, Oct. 12, at the Medical Center's Fairchild Auditorium.

Attorneys have been retained by the group to help with organization and to determine the legal subcommittee, although "there are no plans for litigation now."

Over $18,000 has been raised to support the group in the last two months, most of the money coming from the $150 dues charged members. To date over 150 community physicians have joined the group.

According to Dr. Sidney Hecker of the Palo Alto Medical Clinic, the Clinic's executive committee has pledged to support the group, and is encouraging Clinic members to join on an individual basis.

In addition, members of the group have met with Palo Alto Mayor Scott Carey and the City Council, and with Dr. Peter Bing, chairman of the Stanford University Board of Trustees.

The City Council is "committed to preserving the concept of a community-access hospital," said Cooney, who practices hematology and internal medicine in Palo Alto and is a member of the clinical faculty at the Medical School.

The community physicians group was formed in response to the Aug. 1 decision by the Hospital Board of Directors reaffirming a closed medical staff policy in the Hospital-based clinical services restricted to faculty physicians.

In its decision, the Board said it was persuaded by arguments that "a closed-staff policy is essential to the successful. . .research and teaching missions of the School of Medicine."

The Hospital-based clinical services in question include anesthesia, cardiology, neurology, and pathology laboratories, the radiology service, and all other specialized laboratories.

These services have been restricted to full-time and part-time paid faculty, except for 41 community physicians who qualify for privileges under the 1968 Palo Alto city contract which granted full control of the Hospital to Stanford University.

- more -

Medical and surgical services are open to community physicians who are members of the medical staff and admit patients to the Hospital. There are 550 community physicians, including the 41 with access to clinical services, who are members of the medical staff.

Under the contract, clinical privileges to community physicians will gradually diminish as the 41 members of the "affinity group" retire.

The prospect of diminishing privileges to laboratories and specialized equipment has been a source of concern for many community physicians who specialize in fields encompassed by the clinical services.

"The board's memorandum (reaffirming the closed medical staff rule) says, 'You may not practice the new technology of medicine in this community', " said Cooney.

As a result young physicans will not come here to practice, and private clinics, such as Palo Alto Medical Clinc, will have difficulty in renewing their medical staffs, he said.

"The variety and quality of medical care will diminish," he said, as will the freedom to choose one's doctors and consultants. "In the future, the use of house staff and students will be mandatory for all patients who enter Stanford Hospital."

When there is no competition from private clinics, Stanford "will be able to spread the cost of teaching and research to the patient," said Cooney. The increase in the cost of medical care at Stanford "is tempting, almost irresistible, inevitable," he said.

Cooney said we would like to see the present membership of the affinity group maintained at present levels, with community physicans who have access to the clinical services replaced as they retire.

"Stanford is a unique place where community and academic medicine are practiced under the same roof," said Cooney.

"We regret that a new administration is retreating from this high ground to an arena of fiscal control and political dominance," he quoted from the group's official aims and purpose statement.

"We object to the concept that private physicians and their patients have suddenly become a hindrance to academic pursuits."

The concerns of the community physicians group will be discussed at a meeting Thursday, Oct. 19, between Mayor Carey and Councilman Roy Clay, and University President Richard Lyman, Dr. Clayton Rich, vice-president for medical affairs and dean of the Medical School, and Robert M. Rosenzweig, vice-president for public affairs.

STANFORD—Dr. Joseph P. Kriss, pioneer in nuclear medicine at Stanford University School of Medicine, has been presented the Society of Nuclear Medicine's Western Regional "Distinguished Scientist" award.

The award was made Friday, Oct. 13 at the third annual western regional meeting of the society in Vancouver, B.C. Dr. I. Ross McDougall, associate professor of radiology and medicine, was selected to present the honor, which is given to one individual annually.

Kriss, professor of radiology and medicine, has been on the faculty of the School of Medicine since 1948. He has served as director of the division of nuclear medicine since 1958.

He has authored more than 130 full manuscripts on a wide spectrum of nuclear medicine topics, including research on bone scanning, bone marrow scanning, hematological studies, renal evaluation, Gallium scanning for tumors, pulmonary scanning and nuclear cardiology.

His heart research work is internationally recognized. Kriss was instrumental in promoting the use of a specialized computer for dynamic cardiac studies.

He has also received recognition in the diagnosis and treatment of thyroid diseases, and has made major contributions in understanding the cause of Graves' disease and the prominent eyes associated with this condition.

His reputation is well-known in the management of all thyroid disorders, and patients are referred to him from throughout the U.S.

Kriss is vice chariman and founding member of the American Board of Nuclear Medicine, and currently serves as chairman of the examination committee of the Board.

He is past recipient of the Henry Kaiser Award for teaching at Stanford.

Kriss received his B.S. from Pennsylvania State College, and his M.D. from Yale University. Earlier this year he was named one of eight distinguished alumni of Penn State.

STANFORD—The family birth program is now underway at Stanford University Hospital.

Beginning Monday, October 16, two rooms are available for women who wish "to labor and deliver in a natural setting, surrounded by their families and close friends, but within the security of modern hospital facilities," says Judy Schmidt, R.N., program coordinator.

"Our goal is to provide an emotionally satisfying, yet medically safe, birth experience.

"The family birth rooms resemble warm, cheerful bedrooms in a home," says Schmidt. The rooms, located next to the delivery suite and postpartum nursing unit, have carpeted floors, private baths with showers, and other home furnishings.

Any woman may use the family birth rooms unless her physician anticipates problems with labor and delivery.

She may have any adults present that she wishes, but visitors are expected to be free of any communicable illness or infection.

During a six-month evaluation period, children may be present during labor and delivery, but must be attended by a responsible adult other than the father or labor support person.

Children may not visit newborns or patients other than their family.

Experienced professional nurses, as well as obstetricians and neonatologists, are present to assist during labor and delivery.

Women who choose to deliver in the family birth rooms should receive prenatal education, and must attend orientation sessions at the hospital. Appointments for the orientation can be made by calling 497-5458.

STANFORD—The American Red Cross-Stanford University Blood Center is making plans to move its facility from the current site in the Stanford Industrial Park to a new location adjacent to the Stanford University Medical Center.

The move has been in response to academic program needs within the School of Medicine, and the desire of the Red Cross to have its blood center operations more closely integrated with major teaching centers, according to Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

The University Board of Trustees has approved the academic program for the center. It involves research and teaching in immunogenetics and immunohematology under the auspices of the Department of Pathology.

Also the trustees Tuesday, Oct. 10, approved a recommendation of the committee on land and buildings to lease with an option to buy the Redwood Building at 800 Welch Road for the blood bank relocation. A budget request for building renovation will be submitted to the University trustees at a later date.

Dr. Donald Avoy, director of the American Red Cross Blood Services for the Central California Region said, "the ultimate beneficiary of the proposed move will be not only the Stanford University Hospital patients served by the Blood Center, but also to some degree all of the patients covered within the four-county region.

"This move is consistent with our goals of having our blood centers well integrated into major medical teaching complexes. We hope ultimately to move the San Jose Center closer to the Santa Clara Valley Medical Center."

The blood center, located at 3330 Hillview Avenue in Palo Alto, was created six years ago as a combined effort of Stanford University Medical Center and the Central Regional Red Cross Blood Services Program.

The center's medical director is Dr. F. Carl Grumet, and the associate director is Dr. Edgar Engleman, both members of the Department of Pathology. Currently, they are engaged in research supported by the National Institutes of Health concerning transplantation antigen testing and the genetic control of immunity.

According to Grumet, the center has dual objectives of providing the highest quality clinical banking services along with intensive research efforts in blood banking sciences.

Presently the Blood Center supplies about two-thirds of Stanford hospital's blood product needs, he said. It also conducts specialized blood cell testing for Santa Clara, Santa Cruz, San Benito and Monterey counties.

Grumet said the relocation adjacent to the Medical Center "will vastly improve our communication with colleagues and will facilitate access to specialized programs and equipment available in other medical school departments.

"In addition, the closeness to the hospital should also improve patient care by reducing delivery time of specialized blood products to patients."

Plans for the proposed relocation at Stanford include a marked upgrading of research laboratory space, and a greater effort on the part of Stanford personnel in the recruitment and processing of blood from volunteer donors, according to Grumet.

STANFORD—Linda R. Meier of Atherton and Dean O. Morton of Palo Alto have been appointed by Stanford University Trustees to the Stanford Hospital Board of Directors.

Meier, a 1961 Stanford alumna, has been active in community activities on the Peninsula, and is currently a member of the board of directors of Children's Hospital at Stanford.

Morton is executive vice president of Hewlett-Packard Company.

The new members succeed Dr. Alejandro Zaffaroni of Atherton who has served on the Board since 1965, and Carroll J. Roush of Portola Valley who has served since 1974.

Meier is president of the board of trustees of the Peninsula Center for the Blind, and is on the board of directors of Children's Hospital at Stanford Family Center. She is vice chairman of the Founding Board of the Cardinal Club of Stanford, and past president of the Junior League of Palo Alto.

Morton received an electrical engineering degree from Kansas State University, and a master's degree in business administration from Harvard University. He has served as general manager of Hewlett-Packard's Medical Electronics Division in Waltham, Mass. and general manager of the Medical Products Group. In 1977 he was elected executive vice president and director of the company.

Conrad F. Gullixson of Palo Alto will continue to serve as president of the Board, and John M. Santana, Jr. of Palo Alto will continue as secretary-treasurer.

Frank H. Roberts of Palo Alto will replace Zaffaroni as vice president.

Others reappointed to the nine-member board are Dr. Edward L. Ginzton of Los Altos Hills, Kenneth R. Hansen of Los Altos Hills, Mervin G. Morris of Atherton, and Dr. Clayton Rich, vice president for medical affairs and dean of the School of Medicine.

Members serve terms of one year, but may be reappointed.

STANFORD—Abnormalities in the reproductive systems of men exposed to DES in the womb do not occur any more frequently than in unexposed controls, according to a preliminary study by researchers at Stanford University School of Medicine.

DES is a synthetic form of estrogen originally used during the early 1950's to prevent miscarriages. The hormone was later shown to be ineffective in prolonging pregnancies, and its use for this purpose has since been discontinued.

Some studies have found increased rates of vaginal cancer among the female children of women who took DES during pregnancy, and increased rates of genital and possible semen abnormalities among the male children.

However, the studies in males have not been confirmed by the work done at Stanford.

Drs. Robert Kessler and Robert Andonian of the division of urology found no difference in the incidence of genital cysts and pathological semen quality among 25 DES-exposed men compared to 25 unexposed controls in a recent double blind study.

Kessler and Andonian reported these findings at last year's Pacific Coast Fertility Society meeting, and plan to continue the study.

"There is still a question about what effect DES has on males," says Kessler. "This preliminary study suggests that it has no effect, but only 25 men were examined."

In addition, the possible increase of testicular cancer among these men reported in some studies should be investigated, he says.

Men who know they were exposed to DES and would like to participate in the study should contact the division of urology, 497-5746.

STANFORD—A Philadelphia man has received his third heart transplant in two and a half years, according to Stanford University Hospital surgeons. This is the first time that any patient has received three heart transplants.

The third transplant was performed on Jerome Young, 43, early Friday morning, Oct. 6, 1978. He is in stable condition, and he now has "fairly good chances of longterm survival," according to cardiovascular surgeon Dr. Edward Stinson.

Young's first transplant was performed May 12, 1976 because of extensive coronary artery disease of his own heart.

His second transplant was done Tuesday, Oct. 3, 1978 because of recurrence of the original disease. Stanford surgeons have now performed second transplants for nine patients, and feel the procedure is "clearly appropriate" for unremitting rejection of the heart or return of the disease.

But Young's second heart failed to function strongly and was not contracting sufficiently to maintain body functions. According to Stinson this is a rare phenomenon, but has happened at least once before.

Stinson says such a third transplant may be a "reasonable alternative" in critical situations where the heart cannot function properly and a donor heart is available.

Since 1973 Stanford has transported hearts, outside the body, from donors as far away as Los Angeles. In the present patient, both his second and third hearts were obtained from outside the Bay Area.

The heart is transported by plane with Stanford surgeons accompanying it. It is flushed with and stored in an electrolyte solution, then cooled to near freezing. The technique slows down the metabolic activity of the heart and preserves it during transport.

More than 20 hearts have been transported in this way in recent years.

Since 1968, Stanford surgeons have performed heart transplants in 155 patients, with 66 currently living.

STANFORD—A settlement for an undisclosed amount has been reached in Stanford University's claim against the architectural firm that designed the new wing of Stanford University Hospital.

"A satisfactory resolution of the dispute has been reached," according to John Schwartz, University legal counsel. He declined to disclose the amount of the claim.

"The architectural firm insisted as a condition of the settlement that its terms remain confidential," said Schwartz.

In the claim, the University contended the Texas firm of Caudill Rowlett Scott was responsible for delays in the project, design failures in the building, and that the project was substantially over budget.

The new hospital wing, which now houses intensive care beds and various services including radiology, surgical pathology and postanesthesia recovery, was begun in 1973. It was scheduled to be completed in May, 1975.

Because of code deficiencies and construction delays, patients were not actually admitted until late in 1976. Planning is still underway to complete the building's shell space.

Originally Phase I construction of the wing was to have a total project cost of $9.1 million.

That budget was increased several times, raising the project cost to approximatly $12.7 million.

The total cost of Phase I has been made more than $18 million, due to equipment, activation and new program costs, correction of code and licensing deficiencies, and increased finance charges.

The University filed a demand for arbitration in 1977, and an arbitration panel had been selected during the summer. According to Schwartz, the settlement was reached during discussions in September.

FOR IMMEDIATE RELEASE
STANFORD—

The Stanford Medical School Faculty Senate Monday night, Oct. 2, voted "to sustain its commitment to minority admissions" and to eliminate its Minority Admissions Committee in favor of a single, expanded Admissions Committee.

The new policy becomes effective immediately.

The Faculty Senate reviewed the School's admissions policy in light of the July U.S. Supreme Court ruling in *Regents of the University of California vs. Bakke.*

In the Bakke case, the court held strict racial quotas to be unconstitutional while leaving ample room for the continuation of affirmative-action programs in effect on many campuses.

Stanford Medical School has had a minority admissions program since 1968. The Faculty Senate had set a minimal goal of at least 20% of each entering class from minority groups, specifically blacks, Mexican-Americans, and American Indians.

The Minority Admissions Committee had been responsible for the separate processing, screening, and accepting of these minority students into the entering class.

The new single Admissions Committee will consider both minority and nonminority candidates. Also, while the earlier committee had 12 faculty members and three student members, The new group can have up to 14 faculty members with additional minority representation.

In revising the admissions policy to conform with the guidelines of the Bakke case, the Faculty Senate said it had accomplished these objectives:

• The selection process assures that all positions in the entering class are open to competition among all applicants.

• It assures that the initial screening and the final selection process possess sensitivity and perception to recognize promise and potential among a diverse number of applicants.

• It can adequately evaluate each candidate's special qualities from the standpoint of the School's needs for a diverse and intellectually superior class.

Three panels separate from the Admissions Committee will aid in the selection process: a general panel, a newly created minority panel, and a panel that reviews applicants for the School's Medical Scientist Training Program (MSTP).

application folders will be reviewed by a panel member (general, minority, or MSTP), according to their category, and by a second member from another panel. The purpose is to select about 600 candidates who will be granted interviews.

Interview reports obtained by panel members for both minority and nonminority applicants will be submitted to the single Admissions Committee which will narrow down the final selection to 250 candidates. From this pool the selection of 86 members of the entering class will be made.

The Faculty Senate stipulated certain factors that should be taken into account in selecting the final group of applicants.

They include grades and Medical College Admissions Test (MCAT) scores, other evidence of scholarly achievement, leadership qualities, minority status, gender, and distance traveled in the context of social or economic disadvantages.

"The aim," said the Senate, "will be to obtain a pool of superior candidates who will be about equally qualified and sufficiently diverse to permit the final selection of a balanced, diversified class."

The Faculty Senate, however, voted to form a committee to investigate in more detail the feasibility and possible mechanism of a weighting system for the selection criteria.

In addition, the Senate asked the Admissions Committee to take into account the existence, within the applicant pool, of about 50 to 60 outstanding candidates who will merit immediate acceptance.

Based on past experience, the Senate said, these "super-accepts" will occupy about 30 places in the entering class.

Stanford University School of Medicine receives more than 5,500 applicants a year.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 497-6911

STANFORD—A five-point program to help resolve present differences between community physicians and Stanford University Hospital has been proposed by a community physicians group.

The group has announced it will hold a meeting to discuss its proposals at 8 p.m., Oct. 12 in Fairchild Auditorium in the Stanford University School of Medicine.

In addition, Palo Alto Mayor Scott Carey and Councilman Roy Clay will meet October 19 with three top Stanford administrators to discuss problems associated with the hospital and the community.

The administrators are President Richard W. Lyman, Dr. Clayton Rich, vice president for medical affairs and dean of the medical school; and Robert M. Rosenzweig, vice president for public affairs.

The physicians formed the group in protest against the hospital's restrictions on medical staff privileges in the hospital-based clinical services.

These include anesthesia, cardiology, neurology and pathology laboratories; the radiology service with its diagnostic, nuclear medicine, and radiotherapy divisions; and all other specialized laboratories.

The board of hospital directors touched off the controversy when it reaffirmed a long-standing policy of restricting staff privileges in these services to faculty physicians.

The board said it based its decision on arguments that "a closed staff policy is essential to the successful research and teaching missions of the School of Medicine."

The decision did not affect any community physicians now holding privileges in these specialized services, and did not alter the hospital's "open staff" policy regarding physicians who admit patients to the hospital's medical and surgical services.

- more -

The latter group comprises the majority of the hospital's 550 community doctors. Provisions for appointment of community physicians to the medical staff are stipulated in a contract signed in 1968 when Stanford purchased Palo Alto's holdings in the hospital.

In a letter to community physicians, Dr. David P. Cooney of Palo Alto criticized the board for placing "great stress on the teaching and research missions of the hospital" and clearly placing "less emphasis on patient care, especially by community physicians."

Cooney, who heads the steering committee of the Community Physicians Group, said the local private physicians are concerned about the effect of the board's new attitude on the quality, cost, and freedom of choice of medical care for the citizens of this community.

He said the aims of the group include:

• to preserve and improve the quality of medical care available to the citizens and to preserve their freedom of choice.

• to urge the hospital board to recognize that the hospital is both a community and academic facility.

• to have the hospital board decision with respect to hospital-based clinical services withdrawn.

• to revise the hospital staff by-laws to create a truly self-governing medical staff and establish community representation in the planning and delivery of all hospital services.

• to create regular communication between the medical staff and the hospital board.

The hospital medical staff by-laws were revised last year to conform with recommendations of the Joint Commission on Accreditation of Hospitals. The new by-laws provided a new framework for the organization of the medical staff. They were drafted by a committee composed of faculty and community physicians.

Under the revised by-laws membership of community physicians on the medical staff's executive committee, the Medical Board, was increased.

STANFORD—Classes began Wednesday, September 27 for 86 first year medical students at Stanford University School of Medicine.

Over 50 undergraduate institutions and five foreign countries are represented in the class, which was chosen from a pool of 5600 applicants, according to Karl Gray, director of student affairs.

Universities which contributed four or more students to the first year class include Stanford, Harvard, Yale, University of California at Berkeley, and Cornell.

The half dozen foreign students come from Barbados, United Kingdom, Vietnam, Mexico and the Republic of China.

Twenty percent of the students represent minorities--black, chicano, and native American. Thirty percent are women.

These percentages, as well as the class size, are similar to those of past years, said Gray.

The average age of the students is 23, although a handful of this year's class are in their 30s.

The in-coming class brings to 385 the number of students in all classes of the medical school. Most students will take lecture courses their first two years, and begin clinical work their third year of medical school.

This year, the first clinical year class was increased by five students to 90, in response to a new federal law requiring a once-only five percent increase in this class for all U.S. medical schools.

The law permits the transfer of students from foreign medical schools, or from American schools that have only two-year programs.

According to Dr. John Steward, associate dean of student affairs, the five transfers at Stanford are all U.S. citizens, although three have done work in foreign medical schools.

Two are graduate students with experience equivalent to that of Stanford students beginning clinical work.

Steward said the increase will have "no major financial impact on the school."

Medical students this year pay a total of $1807 each quarter in tuition and fees. Tuition for next year (1979-80) has not yet been determined, said Gray.

STANFORD—Self-defense against heart attack or stroke is the subject of a new skills training book by a Stanford University Medical School professor.

"Because our environment surrounds us with deleterious influences, we need skills to use in our self-defense," says Dr. John W. Farquhar.

The book, *The American Way of Life Need Not Be Hazardous To Your Health*, (208 pp., W.W. Norton, New York, $9.95), teaches individuals how to gain control over their health by introducing them to skills for stress management.

These skills are used later to tackle other health risk areas, including exercise, nutrition, weight control and smoking.

Farquhar, professor of medicine, has directed the Stanford Heart Disease Prevention Program for more than five years. Many of the techniques recommended in the book already have been used successfully in this program and elsewhere.

"There are books on smoking cessation, books on weight control, books on stress management and books on exercise, but generally they have concentrated on why change is needed, not on how to achieve it," says Farquhar. "Relating all of these risk factors to one another is also new," he adds.

Armed with background information on why changes in the average American life-style are necessary for good health, the reader then may pursue Farquhar's practical program for achieving "self-directed change."

The book helps readers to make gradual but permanent changes in everyday living habits, through a series of steps:

- identifying the problem
- building confidence and commitment to change
- becoming aware of negative behavior patterns
- building a personal action plan
- evaluating progress regularly
- maintaining the new life-style

"We often live as if our habits don't matter. They do," says the author, adding "the overwhelming majority of fatal and near-fatal episodes of premature heart attack and stroke are preventable."

The techniques introduced in the book include relaxation exercises to relieve tension, self-contracts for change, achieving support from others, substituting constructive thinking patterns for negative attitudes, and self-rewards for progress.

Farquhar acknowledges that making permanent living changes is not simple, and accepting slow progress is part of the battle, he says.

"It's all right to go three steps forward and two steps back. People must learn to treasure that one step forward," he says.

Farquhar thinks that books may provide one method of effective public health education.

"There is a definite place for health action in this country, but you need a well-informed public," he says.

"It is my deepest hope that someday the quality of public health education will be so excellent, and our society so supportive of healthful life-styles, that we will find it simple to retain our natural birthright of good health. Until that time, this book is one man's attempt to work toward that goal," Farquhar states in his introduction.

FOR IMMEDIATE RELEASE

STANFORD—

If the increase in the number of surgeons in the U.S. continues unchecked, the result will probably be higher fees and also more operations, according to a study published by the National Bureau of Economic Research (NBER).

Conducted by Professor Victor Fuchs of Stanford University and NBER researcher, the study provides "considerable support" for earlier research that surgeons shift the demand for operations.

"Other things equal, a 10% increase in the surgeon/population ratio results in about 3% increase in the number of operations and an increase in price," writes Fuchs in the *Journal of Human Resources'* special supplement on "The Economics of Physician and Patient Behavior."

Fuchs notes that differences in supply of surgeons seem to have "a perverse effect" on fees, raising them when the supply increases.

"Surgeon supply is in part determined by factors unrelated to demand," Fuchs says. Surgeons prefer attractive areas in which to live and practice.

Evidence that some variation of Parkinson's law may be at work in the field of surgery in the United States was presented nine years ago by Dr. John P. Bunker of the Department of Family, Community and Preventive Medicine at Stanford.

In his study Bunker observed there were twice as many surgeons in proportion to population in the U.S. as there are in England and Wales, and proportionately they did twice as many operations.

Another study by Dr. Charles Lewis of U.C.L.A. compared operation rates and surgeons among 11 population regions in Kansas and made the startling observation of three-to four-fold variations in rates for a dozen common operations. Included among them were such operations as appendectomy, cholecystectomy, herniorraphy, and tonsillectomy.

The numbers of operations were shown to vary directly with the number of surgeons and hospital beds, and Lewis suggested that it might reflect a sort of Parkinson's law.

Yet these and other earlier studies were challenged by skeptics on the basis that the meaning of the difference in statistics was not clear.

Fuchs' approach used a much wider data base to conduct a statistical analysis of differences in the supply of surgeons and the demand for operations across the nation as a whole in 1963 and 1970.

-more-

His research used data on the frequency of 11 common operations obtained in the Health Interview Survey conducted by the National Center for Health Statistics. The physician supply figures came from the directory published by the American Medical Association, "Distribution of Physicians in the U.S.," considered reliable.

The relationships of variables that determine physician choice of location, consumer demand, educational level of population, complexity and necessity of procedures, and the effect of supply on price were taken into account.

Fuchs concludes that an increase in the supply of surgeons in a given area results in an increase in demand for operations.

This effect is true even if one takes into account the weakness of some of the data, he says. "Indeed, it should be noted that some of the weaknesses serve to understate rather than exaggerate the extent to which surgeons can shift the demand for their own services."

The finding that when the number of surgeons goes up the operations increase also was true for 1970 and 1963, the years compared.

The effect was present and even stronger when metropolitan and nonmetropolitan areas were studied separately.

The effect of supply of surgeons on the demand for operations was negatively correlated with the level of education of the population. (The higher the educational level, the weaker the effect on demand).

The supply of surgeons affected more strongly a demand for procedures deemed less urgent and less necessary by physicians.

"Surgeons have considerable discretion in choice of location. Their distribution is determined partly by their preferences as consumers," says Fuchs. "Their preference for metropolitan living may reflect the professional attraction of the medical environment."

As a result the distribution of the supply of surgeons is partly unrelated to the underlying demand for operations.

Fuchs also found that when surgeons are plentiful in an area, not only the demand for operations goes up, but also the prices.

"But why don't they raise them even higher in areas where surgeon/population ratios are low?" he asks.

Fuchs suggests a possible explanation: "Their incomes are already satisfactory because of their higher (but not excessively high) workloads, and they have less incentive to induce additional demand."

"The implication for national policy of these results seems striking," he says. "If the surgeon/population ratio should increase (this seems likely if no action is taken), the result will probably be higher rather than lower fees, and also more operations."

Fuchs, professor of economics and family, community and preventive medicine at the Stanford School of Medicine, is presently on leave at the Center for Advanced Study in the Behavioral Sciences at Stanford.

STANFORD—William L. Evans has been appointed director of the Department of Facilities at Stanford University Medical Center.

Evans begins his duties Dec. 7, according to Peter J. Levin, executive director of Stanford University Hospital and Clinics.

Evans, 46, will assume control of a department which is responsible for the maintenance of buildings, grounds and equipment at the medical center. The Department of Facilities has an approximate operational budget of $6 million annually, and about 125 employees.

Since 1973 Evans has served as director of facilities at Fairchild Semiconductor in Mountain View. While there he has managed the operation, rearrangement and expansion of more than one million square feet of space, including planning, engineering, maintenance and plant operations.

At Fairchild he has managed two local and four remote construction projects which are now complete, and two additinal projects underway.

Evans was also a founding partner of the Tech V Corp. of Santa Clara, and is a former facilities manager at Memorex Corp., also of Santa Clara. He is also a former senior facilities engineer at IBM in San Jose and development engineer at Aerojet General Corp. in Sacramento.

A graduate of Cal Poly, San Luis Obispo, Evans succeeds James McNally, who resigned June 30.

STANFORD—Dr. Lars M. Vistnes, associate professor of surgery at Stanford University School of Medicine, has been awarded an honorary fellowship by the American Society of Ophthalmic Plastic and Reconstructive Surgery.

Vistnes, who also is chief of surgery at the Palo Alto Veterans Administration Medical Center, was awarded the fellowship for his work in reconstructing the orbits, or eye sockets, of persons who have lost an eye so that they can wear a prosthetic eye.

The award was presented October 27 at the Society's annual meeting in Kansas City, Missouri. Dr. George Paris, an ophthalmic plastic surgeon at the Menlo Medical Clinic and clinical assistant professor at Stanford, accepted the award in the absence of Vistnes.

According to Paris, Vistnes is one of only four physicians who have received fellowships by the Society.

Another awardee, Dr. Ray N. Berke, clinical professor emeritus of surgery at Stanford, received a Society fellowship in 1974 for his work on ptosis, drooping eyelids.

Vistnes, 51, is a native of Stavanger, Norway, and received his undergraduate and medical education in Canada. He spent his residencies in surgery and plastic surgery in San Francisco hospitals, and was a lecturer in surgery at the University of Manitoba before coming to Stanford in 1971.

In addition to his work on orbital reconstruction, Vistnes initiated the use of a water bed treatment for spinal cord injury patients. He showed that the water bed was more effective than other treatments in relieving pressure which leads to bed sores.

STANFORD—

Compared to the rate in other industrialized countries, about half as many doctors in the United States become general practitioners, while a large number specialize in a single area of medicine.

But this pattern may be changing, since more than 350 training programs across the country now produce family specialists, according to Dr. William C. Fowkes, Jr., associate professor of clinical medicine and head of the division of family medicine at Stanford University Medical School.

Fowkes, one member of a panel of physicians who discussed the issues of how to choose and when to see a physician, said the first step in choosing a doctor is deciding what type of doctor you want.

Dr. Keith I. Marton, assistant professor of medicine, and Dr. Harold C. Sox, Jr., assistant professor of medicine and head of the division of general internal medicine, were the other panelists at the final lecture in the fall quarter Progress in Medicine lecture series at Stanford.

Fowkes advised finding a single primary care provider for the whole family and he stressed the importance of a continuous, ongoing relationship between patient and doctor.

"Health care is very complex," he said, "and you often need someone there to advocate your value system, as well as to 'quarterback' or refer you to the appropriate specialists. Your doctor should help you negotiate with the health care system."

Fowkes named some factors which enter into the choice of a doctor. These include locale, the hospital which the doctor uses, ethnic background, and religion.

"Most people feel more comfortable when their doctor shares some of their values," he said.

Fowkes outlined three styles in doctor/patient relationships which the patient should consider in making a choice; the authoritarian doctor who gives orders to the patient; the doctor who counsels, giving advice and seeking cooperation from the patient; and the mutual partnership where the patient is in control.

- more -

"When buying a car or repairing a house, as consumers we examine the product or service carefully. But when we go to a doctor, we usually passively surrender ourselves. We have to break down the awe towards the physician provider," Fowkes added.

He suggested making a preliminary visit to a prospective doctor's office. During the visit, the patient might look over the facilities and ask questions.

Marton explained that there are no simple rules for deciding when to see a doctor, but he suggested following a few basic principles:

. severity of symptoms - those which do not interfere with daily activities are less likely to require a physician's care

. the test of time - a waiting period will allow an individual to recognize a significant proportion of self-limited symptoms

. therapeutic trial - symptoms which respond to simple therapies, such as home remedies, are less likely to be serious.

Marton added that 85-90 percent of illnesses such as colds and flu, will go away without the intervention of a physician.

Fowkes addressed the problem of medical records in a mobile society. "I always examine carefully the record of a new patient, and I usually give a letter to any patient of mine with a health problem, who plans to travel."

Noting that a significant number of patient visits to the doctor's office arise from nonorganic problems with a social or psychological origin, the panelists referred to the current emphasis on training doctors in allied medical skills such as counseling.

Marton commented that the current trend is away from annual checkups, routine screening and lab tests, towards less frequent examinations.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine and by the members of the Medical Center Council.

The next series of lectures will begin in February.

STANFORD—Progress in understanding rheumatoid arthritis and related diseases will be the subject of a regional meeting of the American Rheumatism Association hosted by Stanford University School of Medicine November 16-18.

The press is invited to attend the meeting, which will be held at the Palo Alto Holiday Inn.

Immunologists from several institutions throughout the western half of the United States and Canada will present their research on the causes and treatment of diseases such as arthritis, systemic lupus erythematosus (SLE), and Reiter's syndrome.

SLE is a generalized tissue inflammation which occurs predominantly in young women. Reiter's syndrome, which involves arthritis, inflammation of tendons, eyelids and urethra, and ulcers of the mouth, is most common among men.

It is becoming more apparent to scientists that genes and the immune responses they control to some extent determine the susceptibility and resistance to several of these diseases.

Indirect evidence of this is found in the association between other diseases and antigens, markers which are found on cell surfaces in all tissues.

The antigens are like badges which enable white blood cells to distinguish between body tissues and foreign materials such as bacteria, viruses and organ transplants. When a foreign agent is identified, an immune response is mounted against it.

But markers on the surfaces of white blood cells also are associated with 35-40 diseases, including ragweed hay fever, arthritis, juvenile onset diabetes, multiple sclerosis, psoriasis, and cancers such as acute lymphoblastic leukemia and Hodgkin's disease.

What determines whether or not a person carrying these markers will develop disease? One theory is that the disease is triggered by an environmental event, such as infection by bacteria or viruses.

For instance, the development of Reiter's syndrome often follows infection by Shigella bacteria.

If this is the case, it someday may be possible to prevent disease in susceptible persons by immunizing against viruses and bacteria.

That is a long way in the future, warn immunologists at Stanford. In the meantime, the search for causative agents and mechanisms continues.

FOR FURTHER INFORMATION CONTACT: Bill Snyder 415: 497-6911

STANFORD—Dr. Stanley N. Cohen, professor of genetics and medicine, has been appointed chairman of the Department of Genetics at Stanford University School of Medicine.

The appointment was announced Tuesday (Nov. 14) by Dr. Clayton Rich, vice president for medical affairs and dean of the medical school.

Cohen has been at Stanford since 1968. He served as head of the division of clinical pharmacology from 1969 to 1978.

He replaces Professor Joshua Lederberg, who left Stanford recently to become president of Rockefeller University in New York.

Dr. Terrence F. Blaschke, assistant professor of medicine and pharmacology, has been appointed the new head of clinical pharmacology.

Cohen is internationally known for his contributions to recombinant DNA research.

In 1973, a group of scientists led by Cohen and Dr. Herbert Boyer, of the University of California at San Francisco, reported the first procedure for constructing biologically active recombinant DNA molecules outside of living cells.

The next year, Cohen and his associates reported the transplantation of genes between different species of bacteria, and the first successful propagation of animal genes in bacteria, using plasmids to transfer the genes.

Plasmids are circular bits of genetic material which can be transferred between bacterial cells. They thus can be used as carriers of new genetic information.

Cohen and Boyer were awarded the 1977 V.D. Mattia Lectureship in recognition of this "immensely powerful approach to the basic and applied molecular genetics of higher organisms."

Cohen's group recently has reported methods for transferring animal genes into bacteria in such a way that biologically active proteins are produced.

This may aid scientists in constructing "bacterial factories," clones of bacteria containing mammalian genes which can mass-produce valuable substances such as insulin and other hormones.

In addition to his gene-splicing work, Cohen directed the development of the clinical pharmacology program at Stanford. He received the 1970 Burroughs Wellcome Scholar Award in Clinical Pharmacology, which supported research and teaching in the new division.

A native of Perth Amboy, New Jersey, Cohen received his bachelor's degree from Rutgers University in 1956, and his medical doctorate in 1960 from the University of Pennsylvania School of Medicine.

He served on the staff of the National Institutes of Health, and was a member of the Department of Developmental Biology and Cancer at Albert Einstein College of Medicine before coming to Stanford.

Cohen is a member of the American Academy of Arts and Sciences, and numerous professional societies. In 1975, he was chosen as a faculty scholar of the Josiah Macy, Jr. Foundation.

He has been involved with the development of safety guidelines for research with recombinant DNA molecules, and served on the committee of the National Academy of Sciences that in 1974 recommended deferral of certain kinds of gene transplantation experiments.

STANFORD—Diseases caused by impaired communication among cells, and the usefulness of interferon will be among the topics discussed at the Big Game medical alumni meeting at Stanford University School of Medicine Friday, November 17.

Three morning symposia will be held at the Sherman Fairchild Auditorium of the Medical School beginning at 8:30 a.m.

Edward Rubenstein, M.D., professor of clinical medicine and associate dean of postgraduate medical education, will discuss the dysfunction of a previously unrecognized mechanism of cellular self-government which accounts for many common diseases, including obesity, diabetes, hyperthyroidism and even cholera.

The usefulness of interferon as an antiviral and antitumor agent will be discussed by Thomas C. Merigan, Jr., M.D., professor of medicine and head of the division of infectious diseases.

Interferon is a natural body substance which is being tested as a treatment for herpes zoster infection, chronic hepatitis, and some forms of cancer.

Paul F. Basch, Ph.D, associate professor of family, community and preventive medicine, and director of the division of international health, will present advice to travelers about microbial infections.

A noon reception and luncheon for alumni, associates, faculty and spouses will be held in the Palo Alto Holiday Inn. The featured speaker will be William H. Clark, M.D., a physician in internal medicine at the Palo Alto Medical Clinic. Reservations are necessary for the luncheon.

The Big Game meeting is part of the Medical School's postgraduate medical education program and is sponsored by the School and the Stanford Medical Alumni Association.

STANFORD—For the person over 65, modern medical care provided by hospitals can "inadvertently prolong death" as easily as it can relieve suffering or restore health.

American medicine has produced thousands of medical and surgical "miracles." But this same emphasis on using science to cure has produced a steady stream of elderly patients "who were saved by science only to end up in a convalescent hospital," says Dr. Louis Shattuck Baer, clinical professor of medicine emeritus at Stanford University School of Medicine.

Baer, a family practitioner for over 30 years, has written a practical guide to help these patients, entitled *Let the Patient Decide—A Doctor's Advice to Older Persons* (The Westminster Press, 1978, $4.95).

"My older patients are nearly unanimous in telling me that 'the real enemy' they most fear is total senility, or total invalidism or confinement in a nursing home, not a sudden death or a short final illness," he says.

Unfortunately, the technological imperatives in many large American teaching hospitals "drive medical practitioners to intervene 'because they can, not because they should.' "

In case of cardiopulmonary arrest the prevailing social mores demand that "if you do not know positively that the patient's brain is permanently damaged, or that he is obviously dying, you must give him the benefit of the doubt and immediately institute vigorous, and if necessary, prolonged attempts at cardiopulmonary resuscitation," says Baer.

Baer says that "it is you the patients alone who can teach your doctor how you want to die."

Elderly patients can do this in several ways:

. they can prepare a living will, spelling out the limits of treatment, and direct that it be kept at the front of their medical records.

. On entering the hospital, they can alter the conditions of admission, and add directions concerning prolonged resuscitation to the surgeon's and anesthetist's permit to operate and give anesthesia.

. and they can wear a Medi-Alert bracelet that "speaks for you if your brain is so damaged or diseased that you cannot speak for yourself."

"To choose what treatment you desire, you must know the facts," says Baer. "You must also understand the way your doctor feels about you. And you must understand how you feel about your own act of dying."

STANFORD—Dr. Thomas A. Raffin has been appointed medical director of respiratory therapy at Stanford University Hospital, according to Dr. James Theodore, chief of the Division of Respiratory Medicine at Stanford University Medical School. Raffin succeeds Dr. Lawrence Simon, assistant professor of medicine.

In addition, Raffin has assumed responsibilities as associate director of the hospital's intensive care units (North-ICU, Medical-ICU and Surgical-ICU).

Raffin, assistant professor of medicine in the division of respiratory medicine, is now co-director of respiratory therapy with Antonius Van Kessel, who is technical director.

As medical director of respiratory therapy, Raffin is responsible for the overall quality of respiratory care delivered by the department.

"The department serves a vital function in the hospital," he says, "providing respiratory care to approximately 100 patients each day, ranging from critically ill patients requiring ventilatory support to patients with chronic lung disease."

Along with clinical and teaching responsibilities in internal and respiratory medicine, Raffin is actively engaged in scientific investigation and has published over 20 papers and abstracts. His primary research interests deal with the effects and mechanisms of oxygen toxicity on cloned lung cells.

In addition to his basic research, Raffin is involved in clinical investigation in intensive care.

Raffin has been associated with Stanford for the past 14 years with a two-year hiatus during his internship and residency at Peter Bent Brigham Hospital in Boston. Upon his return he was a postdoctoral fellow with the division of respiratory medicine for three years. He received his B.A. from Stanford University in 1968 and his M.D. from Stanford University Medical School in 1973.

STANFORD—A panel of Stanford physicians will discuss guidelines for selecting a doctor at a free public lecture at the Medical Center on Wednesday, Nov. 15.

The fourth and final lecture in the Progress in Medicine lecture series is set for 7:30 p.m. in the Sherman Fairchild Auditorium.

"How to Choose and When to See a Doctor" will be discussed by Dr. William C. Fowkes, Jr., associate professor of clinical medicine and head of the division of family medicine; Dr. Keith I. Marton, assistant professor of medicine; and Dr. Harold C. Sox, Jr., assistant professor of medicine and head of the division of general internal medicine.

Fowkes received his M.D. from Stanford in 1955, has coordinated Area III of the California Regional Medical Program, and currently directs the residency program in family medicine at San Jose Hospital.

Marton received his M.D. from Stanford in 1970, and has served at the Center for Disease Control's Epidemiology Intelligence Service in Los Angeles. A former Robert Wood Johnson clinical scholar, his research interest is in evaluating clinical decision-making and medical technology.

Sox has served at the National Cancer Institute, and joined Stanford in 1973. His research interest has been in finding ways for physicians to make more effective use of information in clinical diagnosis.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine and by members of the Medical Center Council.

ADVANCE FOR RELEASE MONDAY, NOVEMBER 13, 1978

STANFORD—New clues to the destruction of heart muscle by certain cancer-fighting drugs have been found by Stanford University reseachers.

Their work may someday enable physicians to prevent this serious side effect of cancer chemotherapy.

The researchers presented evidence that histamine and catecholamines, body substances involved in the maintenance of blood pressure and heart rate, may play role in heart muscle damage, called cardiomyopathy, which follows the use of adriamycin.

Dr. Michael Bristow, postdoctoral fellow in cardiology, conducted the research with Drs. Robert H. Scott, Margaret E. Billingham and John R. Daniels of the Stanford University School of Medicine.

Bristow reported the results at the 51st scientific session of the American Heart Association in Dallas, Texas, Monday, November 13.

"Adriamycin is the best single agent in cancer chemotherapy." said Bristow. It has an extremely broad spectrum of activity, and is used to treat both solid tumors and leukemia.

However, its side effects on the heart restrict long-term administration of the drug. "The heart falure it produces is a worse disease than the cancer it is used to control," he said.

Adriamycin exerts all of its acute side effects by stimulating the release of histamine and catecholamines.

High levels of histamine were detected in the blood of experimental animals within minutes of giving adriamycin, said Bristow. Histamine caused blood vessels to dilate, and a corresponding drop in blood pressure.

This in turn stimulated a compensatory increase in catecholamine levels, which increased heart rate. Catecholamines are known to damage heart cells, and many of the known effects of histamine suggest that it too might cause tissue damage.

Bristow and his colleagues found that the acute cardiac effects of adriamycin, as well as some of the late destruction of heart tissue could be prevented by drugs which block the actions of histamine and catecholamines.

- more -

They are continuing their studies to determine the relative role of histamine, catecholamines and adriamycin itself in the long-term harmful effects on the heart.

"Our major fear was that the cardiac side effects were linked to the antitumor response of the drug," said Bristow. But if histamine and catecholamines are the culprits, "we may be able to take care of that with appropriate blocking agents, and possibly eliminate cardiomyopathy in this group of patients."

Bristow said that damage to heart muscle occurs to some extent in every patient who takes adriamycin, and that the damage is irreversible.

Usually the damage is subclinical, and the patient doesn't feel any symptom of heart problem. However, once the symptoms occur, the patient's life is in jeopardy. Mortality is 50 percent in patients with symptoms, said Bristow.

To prevent heart failure, every patient receiving adriamycin as part of treatment for cancer at Stanford is checked carefully.

Biopsies and catheterization studies are performed in patients with symptoms of heart trouble, as well as those who have received radiation therapy in addition to adriamycin. Radiation seems to increase the drug's effects.

Careful evaluation of patients has enabled the Stanford group to prevent heart failure due to adriamycin-induced damage, said Bristow.

However, many physicians, particularly those who do not have access to comprehensive diagnostic procedures, are becoming more reluctant to use the drug. As a result, "adriamycin may not be used as much as it should be," he said.

FOR IMMEDIATE RELEASE
STANFORD—

Dr. Clayton Rich, vice-president for medical affairs and dean of the Stanford University School of Medicine since 1971, has requested to be relieved of his administrative responsibilities, University President Richard W. Lyman said Wednesday, Nov. 8.

Dr. Rich advised President Lyman of his desire to step down as vice-president and dean to provide the School with the "opportunity for new leadership."

The dean's resignation will be effective Jan. 1, 1979. He plans to work on issues of public and institutional policy for academic medicine.

Lyman announced that Dr. Lawrence G. Crowley will become acting vice-president and dean of the School of Medicine in January. The president said he would soon form a search committee to conduct a nationwide search for Dr. Rich's successor.

Crowley is a professor of surgery and currently deputy dean of the School of Medicine.

Expressing his personal regret at the dean's decision, President Lyman noted that Dr. Rich's term of office was marked by significant achievements.

These included the development of the programs in Structural Biology and Neurosciences, the building of new facilities in the basic and clinical sciences, and the attraction to Stanford of new faculty leadership in the core scientific and clinical fields.

"These are major achievements, accomplished at a time of rapid change and great stress for medical research and education everywhere," Lyman said. "They testify to Dean Rich's commitment to the proposition that scientific excellence is the essential underpinning for educational and clinical excellence.

"That has been the tradition of the Stanford Medical School, and it must remain its distinguishing characteristic."

In his letter to Lyman, Dr. Rich said that "the changing external environment and the pressures these changes have brought forth, have caused divisions and differences within the School.

"I must regretfully conclude that these can best be resolved and our serious problems dealt with if the School has the opportunity for new leadership."

Dr. Rich came to Stanford from the University of Washington in Seattle where he was professor of medicine, and had served as associate dean for research and clinical affairs, and as chief of staff of the Veterans Administration Hospital.

Dr. Crowley was professor of surgery at Stanford from 1964 to 1974. He became dean of the University of Wisconsin Medical School in Madison that year, but he returned to Stanford in 1977.

11-7-78

—30—

Following is a Nov. 7 letter from Clayton Rich, Vice-President for Medical Affairs and dean of the Stanford School of Medicine, to University President Richard W. Lyman:

I have now been dean and vice-president at Stanford for more than seven years, and consider it a privilege to have been associated with this faculty and university in this way. I believe that a great deal has been accomplished for the School, which now stands as one of the finest academic institutions in the country.

However, the changing external environment and the pressures that these changes have brought forth have caused divisions and differences within the School. I must regretfully conclude that these can best be resolved and our serious problems dealt with if the School has the opportunity for new leadership.

In order to create that opportunity, I am resigning my administrative appointments as vice-president and dean on Jan. 1, 1979. My own plans will be to work on issues of public and institutional policy for academic medicine.

It has been a great pleasure to work with you and many others at Stanford, and with the faculty of the School during these past seven years.

* * *

Following is a statement issued in response to Dean Rich's letter by President Lyman:

Clayton Rich has served as Vice-President for Medical Affairs and Dean of the Medical School since 1971. In that time he has never wavered from the highest standards of intellectual and personal integrity or from devotion to the central purposes of a great university Medical Center.

The accomplishments of Dean Rich's tenure in office will benefit Stanford for many years to come. To mention only a few is to risk overlooking others, but among his important achievements are the development of the programs in Structural Biology and Neurosciences, the building of new facilities in the basic and clinical sciences, and the attraction to Stanford of new faculty leadership in the core scientific and clinical fields.

These are major achievements, accomplished at a time of rapid change and great stress for medical research and education everywhere. They testify to Dean Rich's commitment to the proposition that scientific excellence is the essential underpinning for educational and clinical excellence. That has been the tradition of the Stanford Medical School, and it must remain its distinguishing characteristic.

Clayton Rich's decision to step down as vice-president and dean was made, as he said, to provide the School with the "opportunity for new leadership." His service to Stanford leaves us all in his debt; the view of the Stanford Medical School which he held will continue to guide us in the future.

STANFORD—Dr. Harry A. Oberhelman, Jr., professor of surgery at Stanford University School of Medicine, has been elected president of the State Board of Medical Quality Assurance (BMQA) for the year 1979, according to the BMQA.

Oberhelman, 54, has the longest tenure of any board member, serving since 1970. He recently was appointed to his third term by Governor Jerry Brown.

A graduate of the University of Chicago School of Medicine (1947), Oberhelman was an instructor and associate professor of surgery there before coming to Stanford in 1960.

In addition to his teaching duties, he is head of the division of general surgery, and has authored numerous publications on gastric secretion, peptic ulceration, and Crohn's disease, an inflammatory disorder of the colon.

Oberhelman is a member of the American Medical and Surgical Associations, and the California Medical Association, and the Santa Clara County Medical Society. He also is a director of the Institute for Medical Research in San Jose.

Also from Stanford, Dr. James P. Lockhart, clinical assistant professor in the department of family, community and preventive medicine, was elected president of the BMQA's division of medical quality.

STANFORD—"Designing a Personal Screening Program" will be the subject of the next Progress in Medicine lecture at the Stanford University School of Medicine, on Wednesday, Nov. 8.

The lecture is the third in a series dealing with "You and Your Health: Options for the Medical Consumer." It is open to the public at no charge, and will begin at 7:30 p.m. in the Sherman Fairchild Auditorium.

Dr. David M. Eddy, on the Stanford faculty in both the Department of Engineering Economic Systems and the School of Medicine, will discuss screening tests for cancer, the annual physical examination, and other health maintenance topics.

Eddy received his Ph.D. in engineering-economic systems at Stanford, and his M.D. from the University of Virginia. He has served as a consultant on health screening plans for many organizations, including the National Cancer Institute. His major research has been involved in applying mathematics and economics analyses to clinical decision-making.

The fourth and final lecture in the series is scheduled for Wednesday, Nov. 15, featuring a panel of physicians on the topic, "How to Choose and When to See the Doctor."

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of the School of Medicine and by the members of the Medical Center Council.

STANFORD—Normal bacteria found in the human intestine may alter the therapeutic or toxic effects of various drugs, according to Dr. Peter Goldman, Maxwell Finland Professor of Clinical Pharmacology at Harvard University Medical School.

Goldman will discuss his research on the subject in the 1978 Pfizer Lecture in Clinical Pharmacology at the Stanford University School of Medicine Thursday, November 9.

In studies in rats, "we've shown that there is a difference in the metabolism (breakdown) of drugs given to rats with normal intestinal bacteria, compared to those with no bacteria," says Goldman.

Sulfasalazine, a drug used to treat ulcerative colitis in humans, is broken down by the rat intestinal bacteria into two components, an antibacterial and an antiinflammatory agent.

"The therapeutic action of this drug could be related to its metabolism," says Goldman.

Metronidazol (trade name Flagyl) is a widely used antiparasitic drug which is known to cause cancer in rodents.

"We've shown that the intestinal bacteria in the rats carry out a metabolic reaction that may be implicated in carcinogenesis (development of cancer)," says Goldman.

In his lecture, Goldman will discuss how this research might be applied to increasing the safety and efficiency of medication in human patients, and in reducing some side effects of needed drugs.

The lecture will be held in Room R358 of the Medical School at 4 p.m. It is open to the public.

STANFORD—Nuclear imaging may be far superior to other low-risk techniques for early evaluation of coronary artery disease, according to Stanford nuclear medicine physicians.

However, the nuclear imaging is not recommended for all patients with coronary disease symptoms, nor is it yet recommended as a screening procedure for large numbers of people.

Nuclear imaging involves the injection of radioactive substances in chemical solution into the body, which allows visualization of particular organs or tissues.

Dr. Michael L. Goris, associate professor of radiology, discussed the Stanford work at the recent western regional meeting of the Society of Nuclear Medicine held in Vancouver, B.C.

Since 1976, radioactive Thallium-201 has been used in 207 patients at Stanford. Thallium imaging correctly identified 97 percent of the significant coronary lesions in these patients. In contrast, electrocardiography (EKG) recognized 84 percent.

Thallium is absorbed selectively by the heart after injection into the blood stream. The gamma rays emitted are measured and processed to form images of the heart.

Stanford researchers have been in the forefront of developing computer processing of these images, resulting in clearer, more precise measurement of abnormalities.

"Comparing our results to recent reports, we conclude that computer processing and interpretation of processed data improves the sensitivity of this technique," said Goris.

One of the limiting factors in the use of nuclear imaging for mass screening is the cost of producing the radioactive isotopes, said Goris.

He sees the technique as particularly valuable for those patients with atypical chest pain.

The procedure may be able to rule out the necessity for coronary angiography, which involves inserting a catheter, or narrow tube, through the patient's vein and into the coronary artery.

Angiography is done under sterile conditions and requires admitting the patient to the hospital. Nuclear imaging, on the other hand, may be done as an outpatient procedure with less risk to the patient.

Both procedures involve the same amount of radiation to the patient.

Both procedures involve the same amount of radiation to the patient.

STANFORD—A chemical sprayed on forested areas to prevent the growth of brush can be poisonous to animals and humans and its use should be banned, according to Stanford University pharmacologist Sumner M. Kalman.

Exposure to the so-called phenoxy acid herbicides is associated with headaches, visual and nervous disorders, and a persistent scarring disease of the skin called chloracne, said Kalman, in a report before the North Coast Regional Water Quality Control Board last week.

Relatively low doses of these agents also cause developmental defects, liver damage and death in experimental animals and in accidentally exposed livestock.

In addition, a contaminant of one of the herbicides, TCDD, "is one of the most poisonous chemicals known," said Kalman, only slightly less lethal than botulinus toxin. A dose of TCDD as low as two parts per billion can cause death in monkeys.

Smaller doses of TCDD are known to cause infertility in monkeys and cancer in mice. Certain types of cancer have been found to occur more frequently among Swedish foresters who were exposed to the herbicides 10-20 years previously, suggesting a possible but inconclusive relationship between cancer in humans and the herbicides, he said.

"To put a known carcinogen and toxic substances into land, plants and animals, and water is non-rational," said Kalman.

"The advantage of spraying forest floors with these herbicides over other methods of selective growth would have to be of an extraordinary magnitude in order to outweigh the risks," he said.

Phenoxy acid herbicides were introduced in the 1940s to kill certain plants selectively on grazing and crop lands, and in gardens. During the Vietnam War, the Air Force used a combination of these chemicals, called Agent Orange, as a defoliant. Later, this practice was discontinued due to protest by American biologists.

Then the chemicals came into use "to suppress certain tree growth and the natural resurgence of brush in forests that have been logged," said Kalman.

-more-

2-2-2

Liberal spraying of the chemicals from planes and helicopters enables foresters and logging companies to prevent the growth of brush in favor of new timber.

However, such spraying "ensures contamination of water," said Kalman, through leaching of the herbicides and the contaminant TCDD out of the soil by rain. Smaller organisms take up TCDD, concentrate it, and pass it on to higher organisms.

People, livestock, and wildlife down wind and downstream from the spraying inevitably will be exposed to contamination or poisoning.

"The toxicity appears to be cumulative," said Kalman. "Hence, even small exposures over a long time will cause damage."

TCDD is thought to exert its effects by inducing the formation of enzymes in the liver which in turn convert potentially toxic substances into highly reactive and damaging chemicals.

"If this is the mechanism of its effect, then a single (TCDD) molecule may be enough to cause an irreversible effect on genetic material," said Kalman.

Kalman, professor of pharmacology at Stanford University School of Medicine, has been concerned with environmental contamination by chemicals for several years.

In the late 1960s, he was active in seeking more stringent control of chemical weapons used in law enforcement, such as MACE, and participated in hearings which lead to the ban on DDT use in California. He also has supported the elimination of lead from gasoline.

Kalman's report on the herbicides was made during public hearings in Arcata, California on a proposed change for more stringent water controls on the use of these herbicides.

These hearings will continue for another two weeks, after which the water quality control board will decide whether or not to make the regulations more stringent.

If they are made more stringent, use of the herbicides effectively will be banned, because the users cannot guarantee that no contamination of water will occur, said Kalman.

STANFORD—Dr. Henry S. Kaplan of Stanford University has been awarded the first Medal of Honor of the Danish Cancer Society for his pioneering work on Hodgkin's disease and other human lymphomas.

Queen Margrethe II of Denmark presented the medal to Kaplan October 26 during the celebration of the 50 year anniversary of the Society in Copenhagen.

During the scientific meeting which preceded the award, Kaplan spoke on the advances in the treatment of Hodgkin's disease.

Kaplan, holder of the Maureen Lyles D'Ambrogio professorship in radiology at Stanford University School of Medicine, is internationally known for the radiotherapy techniques he developed which have lead to dramatic gains in the treatment of cancers of the lymphatic system, such as Hodgkin's disease.

Kaplan and his colleagues are responsible for initiation of staging laparotomies and splenectomy, surgical procedures which have improved the evaluation of Hodgkin's patients.

In 1959 Kaplan discovered that lymphomas which developed in mice after exposure to X-ray or chemical agents were in fact caused by latent viruses stimulated by the agents.

Since then, he has extended his study of cancer-causing viruses to humans.

As director of the Cancer Biology Research Laboratory, Kaplan has recently been involved in establishing permanent cultures of human lymphomas and leukemias, and in isolating C-type RNA viruses from established cell lines.

Among Kaplan's honors are the 1969 Atoms for Peace Award, and election in 1972 to the National Academy of Sciences. In 1977 he was awarded the Leopold Griffuel Prize by the Association for the Development of Cancer Research, and the next year he received the Lila Gruber Memorial Cancer Research Award.

STANFORD—Interferon has been used successfully to reduce tumors of the lymphatic system, so-called lymphomas, in patients in a preliminary study by Stanford University researchers.

Reporting in the December 28, 1978, issue of the *New England Journal of Medicine*, the researchers found that injections of the natural body substance resulted in "significant regressions" in three patients with B-cell lymphomas.

B lymphocytes are white blood cells produced by the bone marrow which play a role in the body's immune responses. A cancer in this system is characterized by proliferation of B cells and the formation of malignant growths, or lymphomas, in the lymphatic system.

The research was conducted by Drs. Thomas C. Merigan, Jr., Karol Sikora, James H. Breeden, Ronald Levy, and Saul A. Rosenberg of the Stanford University School of Medicine.

"These observations are preliminary, and additional studies are needed" to establish the usefulness and safety of interferon in treating lymphomas, stated the authors.

However, the response of this particular form of disease was "very consistent with respect to the time of drug administration," said Merigan.

The patients had received no prior treatment, and it was highly unlikely that spontaneous regression occurred in all three cases at the same time, he said.

Two of the three patients have been followed for a number of months, "and remain well, with no evidence of progression of disease," stated the authors.

The study was supported by the National Cancer Institute. It is a forerunner of a $2 million nationwide trial supported by the American Cancer Society to determine the effectiveness of interferon in treating human tumors.

The Stanford study is the first U.S. study to report results, said Merigan.

According to the study, three other patients with a different, rapidly advancing form of lymphoma failed to respond to the interferon treatments. They had previously received drug and radiation treatments. Their disease was unresponsive to further chemotherapy and two of the patients later died.

The inability of interferon to control this form of lymphoma in these patients may have been due to the rapidly advancing nature of their disease, and to their exposure to extensive prior cancer therapy, stated the authors.

- more -

Previous therapy "could compromise the ability of immune elements to cooperate with interferon in a tumor-suppressing action."

Interferon is produced by white blood cells when they encounter foreign substances in the body. Presently, most of the world's supply of interferon is produced from human cells by a laboratory in Finland. Efforts are underway to synthesize the material or isolate the gene for its production.

In addition to its antitumor properties, interferon is a known antiviral agent, capable of improving herpes zoster and hepatitis B infections.

It is not known how interferon causes tumor shrinkage, said the authors. However, there is increasing evidence that it may act either by inhibiting malignant cell growth or by aiding destruction of tumor cells by the immune system.

The importance of interferon in controlling lymphomas is not that it causes greater tumor shrinkage than conventional X-ray treatments or chemotherapy, they stated, but that it works by a different mechanism, perhaps as part of the immune system or via bolstering natural body defenses.

The authors recommended studying the effectiveness of interferon in treating other cancers of the lymphatic system, including Hodgkin's disease, Burkitt's lymphoma, and acute lymphocytic leukemia.

In the meantime, the Stanford group is "continuing to treat other patients with B-cell lymphomas with interferon, both alone and in combination with standard chemotherapies, to see if it can decrease disease and prolong life in these patients," said Merigan.

STANFORD—An ointment for removing diseased fingernails and toenails without surgery, has been developed by physicians at Stanford University Medical Center.

Dr. Eugene Farber, professor and chairman of the department of dermatology and Dr. David South, acting assistant professor of dermatology reported in the December issue of *Cutis* that 35 patients have been treated successfully with the new ointment.

The active component in the ointment is urea, which painlessly dissolves the bond between the diseased portions of the nail and the skin underneath, called the nailbed.

First, the ointment is applied to the nail and left in place for a week under a waterproof dressing. The nail is then easily removed, exposing the nail bed, which may be treated with medication, if necessary.

After exposure, the nail bed hardens within 24 hours, forming a surface almost as hard as another nail.

The standard method used in the U.S. for removal of nails is surgery, says South. However, surgery can be painful and expensive for patients, he says. Anesthesia is required and patients generally lose a day or two from work.

The new ointment has the advantage of being painless, inexpensive, and patients may return to work immediately, he adds.

The process is useful for a wide range of nail disorders including psoriasis, fungal diseases, bacterial and yeast infections and traumatic injuries.

The idea of urea ointment treatment came to Farber during a recent visit to the Soviet Union. There, similar ointments have been used in the removal of fungal nails.

CITY DESKS: The following is an announcement of a forum on recombinant DNA to be held at Stanford on January 13, 1979. The forum is free and open to the public.

STANFORD—A public forum on recombinant DNA research and the relation between science and the public will be held January 13, 1979 from 10a.m. through 5p.m. in Fairchild Auditorium of Stanford University School of Medicine.

The controversial issues in recombinant DNA research and the public's role in developing and enforcing science policy will be the focus of the forum.

Morning session speakers will cover topics such as benefits and risks associated with recombinant DNA research, who makes the decisions on guidelines and controls of research, the relationship of federal regulations and legislation to local control, and the public's role in decision-making.

Afternoon workshops are scheduled to encourage participants to discuss the policy and science issues in small groups with the speakers.

Some workshop topics are science policy issues for educators, the public and science, worker safety and training, and approaches to regulation.

Speakers will include Ronald Cape, chairman of the Board, CETUS corporation; Dr. Ronald Davis, associate professor of biochemistry at Stanford University; Andrew Jameton, lecturer on bioethics, University of San Francisco Health Policy Program; Richard Knox, medical editor of *The Boston Globe*; Dr. Robert Sinsheimer, chancellor at the University of California, Santa Cruz; Susan Wright, historian of science at the University of Michigan, Ann Arbor; and Burke Zimmerman, science consultant in the U.S. House of Representatives.

A broad coalition of organizations is sponsoring the event. Among those involved are the Palo Alto Human Relations Commission, the League of Women Voters of Palo Alto, Common Cause, Consumers Union West, the Palo Alto PTA council and the Department of Family, Community and Preventive Medicine at Stanford.

The forum is funded by the California Council for the Humanities and Public Policy, and is free and open to the public.

Further information and preregistration materials may be obtained by phoning the Stanford University Division of Health Services Research at (415) 497-6426.

STANFORD --How do germs, insects and cells learn to withstand the assault of drugs or chemicals?

This is one of the important questions to which medical scientists are devoting much thought and effort.

The ability of organisms to develop resistance to antibiotics, insecticides and other chemicals is a widespread and serious problem, and one which will increase unless humankind changes the way these agents are used.

New research which helps explain how resistance develops was published in the Dec. 8 issue of *Science*by a team of scientists at Stanford University.

They believe it offers clues to the mechanisms involved, and, warns Dr. Robert T. Schimke, unless the methods of chemical and drug use are changed, the world may "essentially run out of effective insecticides and antibiotics."

Schimke, professor and chairman of the department of biological sciences at Stanford, conducted the research with Randal J. Kaufman, Dr. Fred W. Alt, and Dr. Rodney F. Kellems.

The researchers found that resistance develops by a process of gene amplification.

In this process, genes which enable organisms to survive in the presence of normally lethal chemicals are produced in greater quantities.

Resistance is not a one-step process, says Schimke. It is acquired when chemicals are given at low doses until some organisms show resistance, and then in increasing step-wise increments.

In the experiment reported in *Science,*the researchers studied the development of resistance in cultured mouse cells to the anti-cancer drug methotrexate.

Methotrexate kills cells by inhibiting an enzyme, dihydrofolate reductase (DHFR), which is involved in the synthesis of protein and nucleic acids.

The researchers found that cells which became resistant to the drug had increased production of DHFR.

- more -

The more enzyme produced, the greater chance that some of the enzyme would escape inhibition by methotrexate, and enable the cells to grow.

The increased enzyme was due to increased production of the genes which code for the enzyme.

This process of increased gene production is probably a general characteristic of all living organisms, says Schimke, "and there is no reason to think that resistance won't also occur in human cells."

In fact. methotrexate resistance has been a serious problem in clinical treatment of human tumors, he says.

A similar mechanism operates in the development of bacterial resistance to penicillin, and of many instances of insect resistance to chemical agents.

Many antibiotics and insecticides are administered in precisely the same way as methotrexate was in the Stanford studies--first in low doses until resistance appears, and then in increasing step-wise increments.

This method of administration provides "excellence conditions for resistance to develop," says Schimke.

In a sense, the use of chemicals in this way furthers the development of drug-resistant organisms, he says.

It would be useful to be able to stop gene amplification in these organisms, but it is unclear how this process occurs in bacteria and in higher organisms. It is a fundamental process, "presumably related to evolution," the extent of which was only recognized a few years ago, says Schimke.

At present, the best way to prevent this form of resistance is to modify the use of chemicals and drugs, state the researchers.

This would include using multiple drugs, treatment for only as long as necessary and with drugs not retained in the environment, and using a second set of multiple drugs if resistance develops.

Countering resistance is an important part of ensuring humankind's survival, says Schimke. "Many people may think of humans as the dominant species, but we're actually in a tenuous long-run battle with the insects and the bacteria,"he says.

STANFORD—Research to Prevent Blindness (RPB), Inc. has presented the Division of Ophthalmology at Stanford University Medical School a $7,500 grant to continue its studies into various eye diseases.

The award brings to $42,500 that RPB has donated to Stanford in the past 10 years.

Dr. A. Ralph Rosenthal, head of the Division of Ophthalmology, said such grants are aiding eye research in saving the sight of thousands who once would have been blinded by common eye disorders. He noted that similar research has resulted in developments in ophthalmic surgery and medical therapy.

Stanford is one of more than 50 medical schools in the U.S. to receive RPB funding. To date, more than $36 million has been distributed by RPB and is the world's leading voluntary organization in support of eye research.

EDITORS: Photos available if not included with story.

STANFORD—"We were very pleased with the way it went at Stanford." That's the way Hardwin and Oriana Mead described the birth of their second child recently in the family birth room at Stanford University Hospital.

Theirs was the first birth in the new rooms, which opened Oct. 16. Located near the postpartum unit on the third floor of the hospital, the two rooms are available for any woman who wishes to have her baby with her family and friends around her, and whose doctor doesn't anticipate any complications.

Mrs. Mead had her first child, Lowell, at home. But when the second came along, the doctor who had been present at the first birth was no longer in the area. So the Meads decided to try Stanford.

"We doubted it could come off as well the second time," explained Mrs. Mead. "I've never had a hospital birth, but I have seen them, and usually the doctors and nurses tend to dominate the situation.

But in the family birth room, Mr. Mead was allowed to act as labor coach, aiding his wife in her breathing and pushing. A friend who was present recorded the birth on film.

The delivery was attended by Dr. Don Creevy, a community obstetrician, and nurse Marie Smith. Resuscitation equipment was in the room, and back-up help from hospital pediatricians was available in case of sudden complications.

For the most part, Creevy and Smith stayed in the background. Only when the membranes ruptured, and meconium, or infant fecal material, was found in the water which had surrounded the baby did they intervene.

Creevy was concerned that the baby may have breathed meconium with the water, potentially causing an infection in his lungs.

Usually, the mother is taken quickly to a regular delivery room when complications like this arise. But in this case there was no time. "The baby was already crowning," said Mr. Mead. "Two more pushes and he was out."

Immediately, Creevy called in the pediatricians. They examined the baby's lungs for meconium with a tube inserted through his trachea. The lungs were clean.

Fifteen minutes later, new-born Paul was in his mother's arms, and two-year-old Lowell had joined them on the bed.

- more -

"This is a complication far more desirably handled in the hospital than at home," said Creevy. "In my experience, people who do home births generally have neither the expertise nor the equipment to handle problems like this."

"We would have been worried about this complication had we been at home,"said Mr. Mead, who is a medical student at Stanford. "We were glad we were at Stanford."

The baby needed to stay in the hospital overnight for observation, so after a couple of hours, Mrs. Mead and he were moved to the postpartum unit. The family birth rooms can be used for up to six hours of recovery if no other woman is waiting to deliver.

So far, nearly 20 women have given birth in the new rooms, and several couples are on the waiting list, according to Judy Schmidt, R.N., family birth room coordinator.

Women wishing to use the rooms are required to attend orientation sessions at the hospital given by a nurse. Perinatal care courses offered in the community are also recommended.

Creevy has attended four births in the family birth rooms, and "all have been excellent and delightful," he said.

"The nurses I have worked with are among the very best." They have shown great warmth and empathy for the family, "which is important in a setting where people are interested in the quality of the birth experience," he said.

In addition, all four families seemed to be delighted with the experience, he said. What makes the family birth room so congenial to them is the privacy and the presence of a window, and being able to choose whom they want to be present, he said.

"One woman in the midst of labor looked around the room and said, 'Gosh, this is just like being at home!'" said Creevy.

FOR IMMEDIATE RELEASE

STANFORD—

A liaison committee to review the relationships of the Stanford University School of Medicine and community physicians has been formed, according to Dr. Lawrence G. Crowley, deputy dean.

The purpose of the committee is to make recommendations that "can preserve and build an effective relationship between the School and the practicing physicians in the community," he said.

Among the items for review will be a controversial decision made by the Stanford University Hospital board of directors last August. The board affirmed an existing policy which restricts access to certain hospital-based services and laboratories to faculty only.

"It is obvious that an early focus will be upon the circumstances, applications, and problems resulting from the policy decision of the board of Hospital directors," said Crowley.

"However, I hope we can broaden our discussions to include all relevant aspects of the relationship between the School and the community physicians," he added.

Relationships between the Medical School and community physicians have been strained since the board's ruling on the Hospital-based clinical services. Present medical staff members are not affected by the decision, but the prospect of diminishing privileges to laboratories and specialize equipment has been a source of concern for many community physicians who specialized in fields encompassed by these services.

The community physicians who practice in Stanford University Hospital last August formed Community Physicians for Patient Care to carry out discussions with Stanford on the closed-staff policy and other issues.

Crowley announced Stanford's desire to form the committee in a letter to Dr. David P. Cooney, chairman of the steering committee of Community Physicians for Patient Care.

The liaison committee is expected to begin its deliberations in January, 1979, Crowley said. Its membership will include community and faculty physicians who will be joined by Hospital Executive Director Peter Levin and University Vice-President Robert Rosenzweig.

- more -

Crowley wrote that Stanford University President Richard W. Lyman is interested in fostering the activity of this committee and has designated Rosenzweig to attend its meetings. The board of Hospital directors is similarly interested. It is likely one or more members of the board will participate.

"The goal of the committee," wrote Crowley, "is to review and make appropriate recommendations regarding the relationship of the School of Medicine—in particular its overall educational program—with the community physicians practicing at Stanford University Hospital, most of whom already participate in the educational programs of the School.

"I hope that we would be approaching all these relevant issues from the broad perspective of how we can preserve and build an effective relationship between the School and the practicing physicians in the community."

Earlier this year the Community Physicians for Patient Care issued a statement of its aims and purposes. "Twenty years ago Stanford Medical School entered this community with the unique and high-minded philosophy that a combined and community facility offered great benefits to all affiliated groups," the statement said.

"In an atmosphere of mutual respect and cooperation this daring idea worked. We hold that this ideal is still valid."

In view of the new developments, talks between Stanford and the Palo Alto Medical Clinic concerning a possible formal educational affiliation have been postponed indefinitely, Crowley said. Palo Alto Clinic physicians will now serve on the new committee.

But the discussions with the Clinic, held over the past six months, "have been relevant and helpful toward providing a better understanding of the goals, dynamics, and problems of our two institutions," he said.

Community physicians on the liaison committee are Walter Arons, Walter Bortz, David P. Cooney, Robert W. Jamplis, and Burt McDowell.

Faculty members are John A. Collins, Lawrence G. Crowley, Philip C. Larson, Kenneth L. Melmon, and William Northway, Jr.

Crowley in his letter suggested that the committee might be expanded to include one community physician who might not be a member of Community Physicians for Patient Care.

STANFORD UNIVERSITY NEWS SERVICE STANFORD, CALIFORNIA 94305 (415) 497-2558

FOR INFORMATION CONTACT: Bob Beyers

FOR IMMEDIATE RELEASE

STANFORD—

The Stanford Board of Trustees has approved an 8.9% increase in general tuition, room and board rates for 1979-80, but softened a proposed 27.6% increase in tuition for new M.D. students.

At its regular meeting Tuesday, Dec. 12, the board approved administration recommendations for an increase in general tuition to $5,595 from $5,130 a 9.1% hike, and an increase in room and board to $2,354 from $2,169, an 8.5% gain.

Developed in accord with President Carter's wage-price guidelines, the 8.9% overall increase compares with a 9.5% hike for the current academic year.

Tuition in the M.D. program of the School of Medicine will increase to $6,174 from $5,388 for continuing students, a 14.6% gain.

The administration had recommended a 27.6% tuition increase to $6,873 for first-year M.D. students, indicating this was needed to restore past relationships between Medical School educational costs (estimated at $35,200 for 1978-79) and tuition (which provided about 21% of these costs in 1972).

Deferring final action on M.D. tuition, the board said the rates should "be set so as to meet the tuition objective proposed over a three-year period."

The final formulation will be subject to approval by Board President Peter Bing, University President Richard W. Lyman, Finance and Development Committee Chairman William Timken, and Academic Affairs Committee Chairwoman Barbara Finberg.

In the School of Law tuition will increase to $5,744 from $5,280 an 8.8% gain.

Wage-Price Guidelines

A background paper circulated to the Trustees states the University has made a "good faith" effort to follow the President's wage-price guidelines even though these raise "serious conceptual and calculational difficulties."

The weighted average of Stanford tuition and room and board rate increases over the two-year base period set by the guidelines is 10.7%. This has been reduced by 0.5% in accord with the national formula on prices and by an additional 1.1% "wage decelerator" detailed in the guidelines, yielding an overall figure of 9.1%.

While some increases are above this figure and others below, the weighted average for the entire package is 9.1%. This is within the guidelines "insofar as we have been able adequately to understand and apply (them) to Stanford's recent past and present plans," the background paper notes.

Undergraduate Admissions

For several years Stanford has been the first major private university to announce its tuition rate increase. The current (1978-79) costs of attending Stanford and those independent institutions most often selected by undergraduates admitted here compares as follows:

- more -

Tuition, mandatory fees, room and board 1978-79

Harvard	$7,505
Yale	7,500
MIT	7,435
Stanford	7,300
Brown	7,240
Princeton	7,217
Dartmouth	7,145
Northwestern	7,025
Cornell	6,890
Cal Tech	6,447
Pomona	6,444
USC	5,878

Stanford will continue to meet the demonstrated financial need of all freshmen admitted to the University. Admissions decisions are made without regard to financial need.

About 55% of all undergraduates receive financial aid. This currently totals about $14 million annually. About $11 million comes in grants and scholarships, while $3 million represents subsidized loans and jobs during the school year.

Despite increasing tuition, recent studies at Stanford have shown that families at the $20,000 and $30,000 income level are expected to contribute a smaller percentage of their income toward University costs than was true in 1970-71. This reflects adjustments made in College Scholarship Service need-assessment formulas adopted in 1975 and followed by Stanford.

Nationally and at Stanford the newly passed Middle Income Student Assistance Act will provide additional support to students and parents. The Basic Opportunity Grant provision has raised the family income limit for recipients to $25,000 from $15,000.

The Guaranteed Student Loan program provides an interest subsidy with no family income limit nationally.

M.D. tuition

Medical School officials have indicated that increased financial assistance will be available to assure that students are not prevented from attending Stanford for financial reasons.

In accord with recommendations from a faculty committee, tuition will be charged M.D. students for 13 quarters, regardless of the number of quarters registered up to a total of 16. (Three quarters constitutes a normal academic year.)

In recent years, Stanford M.D. graduates have averaged 13 quarters, with many students cutting short their education to save money. The new policy will encourage stuents to participate more fully in elective scholarly activities.

STANFORD—Using gene splicing techniques, Stanford University scientists have achieved the first biological expression of mammalian genes in bacterial cells.

Their research, reported in the October 19 issue of *Nature*, is an important step aiding scientists in constructing "bacterial factories," clones of bacteria containing mammalian genes which can mass produce valuable substances such as insulin and other hormones.

A public statement on the research is being released now in response to queries from press organizations.

The research was conducted by Annie C.Y. Chang, Jack H. Nunberg, Randal J. Kaufman, Henry A. Erlich, Robert T. Schimke, and Stanley N. Cohen. The research was supported by grants from the National Institutes of Health, the American Cancer Society and the National Science Foundation.

The transfer of genes from higher organisms to bacteria has been possible for several years using recombinant DNA (gene splicing) techniques, but this is the first time a biologically active protein was produced in bacteria by transferred mammalian genes.

Previous attempts have resulted in the production of "hybrid" proteins, molecules which contain bacterially-derived as well as mammalian sequences.

When the mammalian components of such proteins were separated from the bacterial components, they sometimes were immunologically reactive. In other words, they reacted with antibodies made against the natural protein.

However, data presented in the *Nature* article indicate that only a small part of the protein is necessary to get reaction to the antibodies. On the other hand, biological activity requires that the proteins function as they would naturally.

The Stanford group experimented not with a hormone, but with an enzyme, dihydrofolate reductase (DHFR), which is involved in DNA metabolism.

The aim was to introduce the mouse gene for DHFR into cells of the bacterium *E. Coli*, and to test whether the bacteria would then produce mammalian DHFR.

- more -

Some of the bacteria into which the mouse gene for DHFR had been introduced could grow in the presence of the antibiotic trimethoprim, which normally inhibits the growth of bacterial cells.

This suggested that the surviving bacteria were not only capable of decoding the mouse DHFR gene but that the protein produced by the bacteria was biologically active.

Protein isolated from these bacteria "has enzymatic properties, immunological characteristics, and molecular size characteristic of the mouse dihydrofolate reductase," wrote the researchers.

According to the article, the production of this biologically active and functional protein was a matter of having the correct DNA sequences which allow production of a separate rather than a hybrid protein.

Knowledge of these correct DNA sequences should enable scientists to get biologically functional expression from other genes, and help define factors that influence biological expression of genetic information in both higher and lower organisms.

The research was carried out in the laboratories of Stanford scientists Stanley N. Cohen and Robert T. Schimke.

Schimke, professor and chairman of the department of biological sciences, is known for his earlier work in developmental biology and for his studies of the mouse dihydrofolate reductase gene.

Cohen, professor of genetics and medicine, and chairman of the department of genetics, is well-known for his contributions to the field of genetic recombination.

In 1973, a group of scientists led by Cohen and Dr. Herbert Boyer, of the University of California at San Francisco, reported the first procedure for constructing biologically active recombinant DNA molecules outside of living cells.

The next year, they reported the first successful propagation of animal genes in bacteria.

NEW VISTAS IN PSYCHIATRY:

THE NEW BEHAVIORAL THERAPIES

One recent arrival to the battery of psychiatric tools is behavioral therapy. Essentially, it is a means of helping patients change behaviors which are destructive, undesirable, or otherwise debilitating. Behavioral therapies are commonly used to help people stop smoking, lose weight, or cure them of insomnia. Relaxation training can relieve a variety of symptoms which result from stress. This is the third of three articles on how behavioral therapies are used to help patients at Stanford's department of psychiatry.

STANFORD—How do you lower your blood pressure, relieve chronic anxiety, asthma and headaches, eliminate phobias, insomnia, nervous tics and some sexual problems?

By learning how to relax.

Many of these problems are symptoms of stress—fast-paced living, competition, sex role confusion—and can be relieved simply by easing the stress.

"Relaxation is a way of reducing stress and anxiety that have multiple effects on all body systems," says Dr. Alan Brauer, director of the Stanford Stress Reduction Clinic.

Patients at the clinic are taught a variety of relaxation techniques, including exercises in which muscles are sequentially tensed and relaxed, autogenic training (talking to different parts of the body silently), self-hypnosis, meditative and breathing techniques, and biofeedback.

According to Brauer, biofeedback is the most popular among patients. "Biofeedback has certain advantages over the other techniques," he says. "It gives precise information about what happens during relaxation in a way that is very appealing to many patients."

Electrodes placed on the forehead and hands send body signals to a computer, which records them graphically and plays them back as audible tones.

The tones drop in frequency when the patient relaxes, reflecting decreased muscle tension, slower heart beat, and warmer skin temperature.

Handwarming is particularly useful in relieving headaches. "Sometimes just teaching handwarming can reduce migraine pain in persons who have been suffering for 25 years," says Brauer.

When combined with medication, relaxation has also been effective in bringing down high blood pressure, according to studies conducted by Dr. Stewart Agras of psychiatry and the Stanford Heart Disease Prevention Program.

"We don't know what the relaxation response is, but its results seem to be similar to the effects of transcendental meditation and hypnosis," says Agras.

- more -

The group is currently testing the effect of relaxation, lowered salt intake, and weight loss on mild hypertensives who are not on medication to see if the combined approach is powerful enough to take the place of drugs in these patients. Other behavioral techniques are used to treat anorexia nervosa, an eating disorder characterized by excessive dieting to the point of starvation.

Patients, most commmonly teen-aged girls, are taught to control their weight by counting the number of bites they take during meals and plotting them on a graph opposite weight gain. From the graph, they can tell how much they have to eat in order to gain weight.

Similar techniques are used to produce the opposite effect, weight loss, in obese people.

However, in the case of anorexia, behavioral techniques are not enough. Excessive dieting is often a symptom of deeper family problems, such as dissension or unhappiness between parents, says Dr. Joellen Werne, a Palo Alto psychiatrist who treats anorexic patients at Stanford. Family therapy is therefore required to successfully resolve the symptoms.

Family and group psychotherapy is also used at Stanford to treat severe psychiatric disorders, to resolve communication problems between couples, and to help patients with life-threatening illness face the prospect of death.

Group therapy operates on the principle that most people who seek professional psychiatric help have some significant problem in relating to others, says Dr. Irvin Yalom, professor of psychiatry at Stanford.

Through group interactions, patients are helped to understand and correct maladaptive interpersonal behaviors and improve communication with others.

In the case of cancer patients, group therapy enables them to confront death, and "move into a mode of existance that is richer than the one they experienced prior to their illness," says Yalom.

"They are able to trivialize the trivial, to assume a sense of control, to communicate more openly with families and close friends, and to live entirely in the present rather than in the future or past."

NEW VISTAS IN PSYCHIATRY:
STRENGTHENING THE MOTHER-INFANT BOND

One of the current frontiers of psychiatric research is focussed on the period immediately after birth. Researchers are exploring both the waking and sleeping lives of newborns for clues to life-threatening physical disorders, such as apnea (ceasing to breathe), and to behavioral problems which may emerge later in life. This is the second of three articles on research conducted by Stanford's department of psychiatry.

STANFORD—If a baby is touched and picked up often, will he be a happier baby than if he is left in the crib all day?

Will hanging bright mobiles over the baby's crib help increase his intelligence?

Are day-care centers beneficial to children?

There are compelling arguments to support both sides of these questions. Fact is, no one knows for sure what effects early stimulation has on human development.

However, research is beginning to shed light on the importance of some kinds of stimulation in physical development and in the mother-infant bond.

In studies begun in 1967, Dr. Herbert Leiderman, professor of psychiatry at Stanford, and his colleagues found that early separation of premature infants from their mothers had an adverse effect on the way the mothers later handled their children and on the way they felt about themselves.

Five years later, a follow-up of 25 families with premature and full-term infants found no long-term effects on either the mother or child, says Leiderman.

However, prematurity itself seems to be associated with a higher incidence of adjustment problems among these children as they grow older.

These studies helped to "revolutionize the psychosocial atmosphere of care-taking of high risk infants," says Leiderman. Today, Stanford and most hospitals in the U.S. allow families to observe and hold their infants in premature nurseries.

– more –

Other studies conducted at Stanford have found that moving and touching babies are important in aiding cognitive development and improving their ability to deal with stress.

Dr. Annellese Korner and her colleagues have found that "when a crying baby is picked up and put to shoulder, it promptly stops crying and becomes visually alert. Under these circumstances, most infants will begin to scan the environment, including their mother."

Korner contrasted the effects of body contact and movement stimulation, and found that movement was the most potent factor in soothing and making the infant visually alert.

As an outgrowth of these studies, Korner developed gently oscillating waterbeds for premature infants to compensate for the movement stimulation they would have had in the uterus.

One benefit of the waterbeds has already been established, says Korner. They reduce the frequency of apneic episodes, periods when these infants stop breathing.

Korner and her associates are now studying the effect, if any, of waterbed stimulation on the infants' maturation and development.

Early physical contact also seems to be important for later abilities to cope with stress.

Researches in Dr. Seymour Levine's lab at Stanford have found that rats which are handled soon after birth deal with later stress better than those which are left alone.

These findings "suggest that infantile stimulation endows the organism with the capacity to make finer discriminations of relevant aspects of the environment," says Levine, "enabling it to respond more appropriately to the demands of the environment, including making appropriate responses to stress."

Physical stimulation does not only have come from the mother. Mother's helpers, whether they be grandparents, neighbors, or siblings, "also have a distinct contribution to make to the social development of children," says Leiderman.

In studies of children in Kenya, Leiderman found that multiple caretakers enhance the cognitive development and learning of infants during the first year of life, even under the most economically deprived conditions.

NEW VISTAS IN PSYCHIATRY:
EXPLORING THE HEREDITARY FACTOR

Psychiatry has made dramatic advances in the last 25 years, particularly in the development of new drug therapies for patients with mental illness. Knowledge of brain chemistry is providing clues to the relation between behavior, physiology and genetics. This is the first of three articles on how these developments are being reflected in the work of Stanford's department of psychiatry.

———

STANFORD—What determines behavior? Are feelings such as anger, fear or anxiety the result of environmental conditioning, or are they programmed in the genes?

There is no definite answer to these questions. However, evidence is accumulating which suggests a clear role for genes in the development of certain behaviors, and environment in the development of others.

In 1974, researchers at the National Institutes of Health found that two groups of a single mouse strain which had been separated since 1947 had developed two very different behaviors. The mice of one group were extremely aggressive and fought any intruder, while the mice of the other were docile and tolerated high crowding.

The mice retained their behaviors, even when they were raised as pups in the litter of the other group.

"This was an astonishing difference in behaviors," says Dr. Roland Ciaranello, professor of psychiatry at Stanford who directed the study. "There was nothing muddy about it. It was due to a genetic mutation."

Similar differences among mouse strains have also been observed in the catecholamine system, a class of body chemicals which controls the response to environmental stress, and which may play an important role in psychiatric illness.

Ciaranello and his colleagues have found that this system is clearly under genetic control. In particular, the group is studying control of the enzymes which synthesize these brain chemicals,and regulation of the hormone adrenaline. Continuation of this work is being supported with over $250,000 in grants from the National Institutes of Health and the National Science Foundation.

- more -

In humans, certain behavioral disorders, such as alcoholism, antisocial behavior, and hyperactivity in children also seem to run in families.

"Are there individuals by virtue of genetic controls who respond too much or too little to stress and consequently exhibit maladaptive behaviors?" asks Ciaranello.

"Our work may give insights into the possible genetic bases of depressive psychosis, manic illness, and schizophrenia," he says.

However, he cautions, "we don't want to label people as having tendencies toward biological illnesses, and pre-ordain them to a specific behavior pattern.

"Even where there is a biological substrate for behavior, environmental influences may be even more important. For instance, simple drug treatment is not as effective as a combination of medication and psychotherapy in producing long-term or permanent changes.

"We should not try to define all human behavior in terms of definite biological systems," he says.

Ciaranello's caution is echoed by Dr. Seymour Levine, director of the Stanford Outdoor Primate Facility. Levine has found that certain social behaviors in the squirrel monkey are determined by the environment.

For instance, the initiation of sex behavior by the male monkey depends on the level of female hormone (estrogen), and has nothing to do with levels of male hormone (testosterone). "The male is synchronized by the female," says Levine.

During the estalishment of a hierarchy among squirrel monkeys, the leader has higher levels of testosterone, but when the struggle is over, he has no more than any other group member. "Dominance alters testosterone levels, not the other way around," says Levine.

Similar alterations in hormonal levels have also been observed in human groups.

"Some behaviors are under rigid biological control, while others are more influenced by the environment. This suggests the importance of the group in integrating the behaviors of its members," he says.

STANFORD—Striking declines in deaths from heart attacks and strokes during the last 10 years have saved an estimated 164,000 American lives, according to Dr. Robert I. Levy, director of the National Heart, Lung and Blood Institute.

"If we had had the same death rates in 1976 which we did in 1968, we would have had 164,000 more deaths in 1976,"said Levy December 2 during a visit to the Stanford Heart Disease Prevention Program at the Medical Center.

Deaths from strokes have dropped over 33 percent in the 10 year period, and continue to decline an average three percent each year. Heart attack deaths have dropped 20 percent in the same period, and each year fall an additional two percent.

"This is a relatively unique phenomenon," said Levy. Western European countries have, at best, steady heart disease-related death rates, and in some countries the rates have actually increased.

Levy cited improvements in emergency resuscitation techniques and coronary care as responsible for some of the decrease in heart disease mortality.

But the greatest factor in the change is related to changes in lifestyle, he said.

"People are more attentive to blood pressure today," he said. Seven or eight years ago, 50 percent of people with high blood pressure were not aware of their condition. Today, 10 million hypertensives are taking effective blood pressure controlling medication.

In addition, the proportion of people in the U.S. who smoke has decreased. Smoking has only increased among adolescent females, said Levy.

Diet has also changed. In the last 10-15 years, consumption of whole milk, butter, eggs and animal fats has dropped. A 50 percent drop in animal fat consumption has been nearly matched by increased consumption of vegetable fats.

"And, today, the biggest leisure habit seems to be exercise," said Levy.

This situation is contrasted with European lifestyles, in which risk factors for heart disease "are not being attended to," said Levy.

Europeans seem to be smoking as much, if not more, than ever. There is no government directed program to lower blood pressure. And consumption of fatty foods is also high.

- more -

Even with the decline, heart disease is still the number one killer in the U.S., said Levy. The American Heart Association estimates that over one million Americans will die in 1978 from all forms of cardiovascular disease.

Levy's visit to Stanford came at the mid-point of a national clinical trial to determine whether reducing cholesterol levels in the blood can prevent or slow down the development of heart disease and heart attacks.

Stanford's Lipid Research Clinic, under the direction of Dr. John W. Farquhar, is one of 12 clinics in the U.S. and Canada participating in the study, which was begun in 1974.

A total of 3,800 healthy male volunteers with high levels of cholesterol are participating in the study, 350 of them at Stanford.

Half of the group are being given therapeutic diets to reduce their cholesterol levels. Cholesterol is being lowered even more in the other half of the group with addition of the drug cholestyramine to their diets.

Cholestyramine is a "roto-rooter sequester," which prevents absorption of dietary cholesterol by the digestive tract, said Levy.

"We do know that when one stops smoking or lowers his blood pressure, the risk of heart disease drops," said Levy. "But what about cholesterol? That's what we're trying to find out."

Levy said that although some of the participants have been followed for five years, preliminary results are not being released because they may jeopardize the rest of the study.

The trial is randomized and double blinded, which means that the doctors conducting it do not know which participants are on the diet alone and which are on diet plus medication. Levy said the findings may not be in until 1983, when all participants have been followed for at least five years.

The Stanford Heart Disease Prevention Program is well-known for its "three communities study," a comprehensive health education campaign which showed that the risk of heart disease could be reduced in the general population.

Recently the program was granted $6.5 million for the next five years by the National Heart, Lung and Blood Institute to study the effect of mass media education programs in cities with populations of 50-150,000.

According to Peter Wood, co-principal investigator of the program, the study may determine for the first time the effect of mediated health education campaigns on actual heart attack and death rates in entire communities.

FOR INFORMATION CONTACT: · Laura Hofstadter 415: 497-6911

STANFORD—

Concern over reports of violent political repression in Argentina recently led Dr. Henry S. Kaplan of Stanford University and other prominent cancer researchers from all over the world to boycott the twelfth International Cancer Congress held October 5-11 in Buenos Aires.

Many of the scientists attended a "counter congress" held in Paris, France during the first two days of the meeting in Argentina.

Kaplan, D'Ambrogio professor of radiology at Stanford University Medical Center, said that many "top researchers in the cancer field" attended the Paris counter congress where about 300 participants discussed both advances in cancer research and repression in Argentina.

Sanctioned by the French Minister of Health, one purpose of the counter congress was to publicize the situation in Argentina, Kaplan explained, but some of the major news services did not attend the counter congress press conference.

One year earlier, Kaplan was one of 700 U.S. doctors and biomedical scientists who signed a petition requesting that the International Union Against Cancer (UICC) change the site of the meeting to a more politically neutral location.

The UICC, a Geneva based group, sponsors the widely attended meeting every four years, according to Kaplan.

Officials of the UICC refused to consider a change, although the request was submitted one year in advance, Kaplan said.

"Many scientists do not like the idea of a boycott," Kaplan explained, "and feel it's more effective to protest within the country in question.

"I don't quarrel with this idea," he added, "but it's counterproductive to debate the merits of each type of protest.

"If one goes and protests, that could be very effective, but to go and remain silent is not."

Kaplan was also a member of a five-person delegation which visited Argentina in late September to express humanitarian concern for more than 4000 individuals who are alleged victims of the present regime.

The delegation carried a list of individuals' names, which they wished to present to government officials. However, the officials, who had agreed in advance to meet with the delegation, refused to do so when they arrived in Argentina, Kaplan explained.

"We couldn't transmit the list directly, but we urged the president of the UICC to request the release of those doctors and biomedical scientists who are in custody, as a major gesture of goodwill," said Kaplan.

- more -

Although the delegation had names of 4000 people of all occupations, a list of 185 medical professionals represented "a constituency we could speak for," Kaplan noted.

According to Kaplan, many doctors have been targets of the military government in Argentina, particularly psychologists and psychiatrists.

"The regime is deeply suspicious of these people," said Kaplan.

When it became clear that Argentine authorities had reneged on their agreements to meet with the delegation members, American, Dutch, British and French embassy officials all made attempts to arrange other interviews, but to no avail, said Kaplan.

The delegation left the list and a strongly worded letter with officials of the UICC, to be transmitted to government officials during the congress.

Kaplan has since received no formal communication from UICC officials confirming that the documents were presented to government authorities.

French lawyer Colette Auger, another delegation member, drew up a special writ of habeas corpus on behalf of the entire list of 4000 people, said Kaplan.

"No charges had been filed against these individuals, none has been brought to trial, and many are thought to have been tortured and executed," he explained.

"The writ said that on this vast scale, under the authority of the court of human rights in Strasbourg, these actions constituted a violation of the Nuremberg laws," Kaplan continued.

"We registered the writ in federal court in Buenos Aires 15 minutes before the court closed on Friday, September 29, and then were escorted to the airport in the French consul general's car to leave Argentina immediately.

"This document formally places the judiciary on notice and places them under an obligation to investigate or become accomplices.

"It's the strongest document of its kind formally lodged in such a country, and it's the most important thing that our delegation accomplished," he said.

Kaplan's only contact with the U.S. government was when he consulted the human rights division in the State Department before his departure from the U.S..

Kaplan said that he doesn't know what to expect now, but he hopes some international pressure will be brought to bear on Argentine authorities.

He also plans to ask "member organizations of the International Council of Scientific Unions, an umbrella group for hundreds of scientific societies, to agree not to sponsor congresses in countries known to be flagrantly violating human rights."

"I have no selective feeling against Argentina," he added, "but the opportunity to express humanitarian concern clearly presented itself at this time," he said.

STANFORD UNIVERSITY NEWS SERVICE STANFORD, CALIFORNIA 94305 (415) 497-2558

FOR INFORMATION CONTACT: Bob Beyers

FOR IMMEDIATE RELEASE

STANFORD—

Following President Carter's wage-price guidelines, Stanford's general tuition, and room and board rates probably will increase 8.9% next fall, student leaders were advised Monday, Dec. 4.

This compares with a 9.5% increase for the current academic year.

The Board of Trustees will take final action Tuesday, Dec. 12, on recommendations developed by the administration.

These call for an increase in general tuition to $5,595 from $5,130, a 9.1% hike, and an increase to $2,354 from $2,169, an 8.5% gain.

Tuition in the M.D. program of the School of Medicine will increase from its present uniform rate of $5,388 to $6,174 for continuing students, a 14.6% gain, and to $6,873 for entering students, a 27.6% hike. (*See details below.*)

In the School of Law, tuition will increase to $5,744 from $5,280, an 8.8% gain.

Wage-Price Guidelines

A background paper circulated to the Trustees states the University has made a "good faith" effort to follow the President's wage-price guidelines even though these raise "serious conceptual and calculational difficulties."

The weighted average of Stanford tuition and room and board rate increases over the two-year base period set by the guidelines is 10.7%. This has been reduced by 0.5% in accord with the national formula on prices and by an additional 1.1% "wage decelerator" detailed in the guidelines, yielding an overall figure of 9.1%.

While some increases recommended are above this figure and others below, the weighted average for the entire package is 9.1%. This is within the guidelines "insofar as we have been able adequately to understand and apply (them) to Stanford's recent past and present plans," the background paper notes.

Undergraduate Admissions

For several years Stanford has been the first major private university to announce its tuition rate increase. The current (1978-79) costs of attending Stanford and those independent institutions most often selected by undergraduates admitted here compares as follows:

Tuition, mandatory fees, room and board 1978-79

Harvard	$7,505
Yale	7,500
MIT	7,435
Stanford	7,300
Brown	7,240
Princeton	7,217
Dartmouth	7,145
Northwestern	7,025
Cornell	6,890
Cal Tech	6,447
Pomona	6,444
USC	5,878

- more -

Stanford will continue to meet the demonstrated financial need of all freshmen admitted to the University. Admissions decisions are made without regard to financial need.

About 55% of all undergradutes receive financial aid. This currently totals about $14 million annually. About $11 million comes in grants and scholarships, while $3 million represents subsidized loans and jobs during the school year.

Despite increasing tuition, recent studies at Stanford have shown that families at the $20,000 and $30,000 income level are expected to contribute a smaller percentage of their income toward University costs than was true in 1970-71. This reflects adjustments made in College Scholarship Service need assessment formulas adopted in 1975 and followed by Stanford.

Nationally and at Stanford the newly passed Middle Income Student Assistance Act will provide additional support to students and parents. The Basic Opportunity Grant provision has raised the family income limit for recipients to $25,000 from $15,000.

The Guaranteed Student Loan program provides an interest subsidy with no family income limit nationally.

In 1977 Stanford started its own Parent Loan Program, charging 8.75% interest, adjustable annually, on loans for tuition and room and board expenses.

The number of participants in this program during 1978-79 totals 121, compared to 116 in its initial year. The average annual loan amount is $4,750, compared to $3,961 a year ago. The maximum loan available this year is $7,000, compared to $6,000 a year ago. The proportion using the maximum has dropped to 34% from 39%. The median adjusted gross family income of borrowers is $35,000 to $40,000.

Studies conducted at Stanford since 1972 have shown that about three out of four students admitted to the University as freshmen who actually enrolled elsewhere chose private institutions of comparable costs. This year the proportion was 77%.

The most frequently selected private institutions were Harvard-Radcliffe, 165; Yale, 89; Princeton, 72; MIT, 45; Brown and Dartmouth, 20 each; Cal Tech 15; Pomona, 14; Northwestern, USC, Cornell, and Georgetown, 10 each. Among public institutions, the leader was Berkeley, 43, followed by UCLA, 18.

M.D. Tuition

The unusually high tuition recommendations for M.D.s in the School of Medicine are designed to restore previous relationships between tuition and the cost of medical education. In 1978-79 this cost is estimated at $35,200 per student per year. The recommended figures of $6,873 for entering students comprises about 21% of the estimated cost next year, the same ratio as found by the Institute of Medicine at Stanford in 1972.

Combined with an anticipated increase in living expenses, the new M.D. tuition will require an additional $400,000 in financial aid. This need can be met from available scholarship and loan funds in the School for the next two years, but additional support may be needed in subsequent years.

According to Deputy Dean Lawrence Crowley, "It is the intention of the School to ensure that attendance here is not prevented by inadequate financial assistance."

In accord with recommendations from a faculty committee, tuition will be charged M.D. students for 13 quarters, regardless of the number of quarters registered up to a total of 16. (Three quarters constitutes a normal academic year.)

"In recent years, Stanford M.D. graduates have averaged 13 quarters, with many students cutting short their education to save money. The new policy will encourage stuents to participate more fully in elective scholarly activities."

The new M.D. tuition rate probably will place Stanford among the 10 to 15 most expensive institutions nationally.

STANFORD—

An elderly woman selling her furniture to pay for medical expenses, when she actually qualified for MediCal.

A man who was entitled to Medicare benefits, but didn't know he could collect for laboratory expenses.

A 76-year old woman carrying four supplementary policies costing over $750 each year.

People such as these now may find help from a new manual on health insurance for people over 65.

The book provides guidance on Medicare and MediCaid coverage, how to choose supplementary health insurance policies, alternative sources of health care in the community, and how to set up a local health insurance counseling program for seniors.

The authors are Leona McGann, assistant professor, and Elizabeth Taft, lecturer, both from the department of family, community and preventive medicine at Stanford University School of Medicine, and Anthony Puentes, a former Stanford undergraduate.

Responses from a survey in a local retirement complex convinced the authors that most seniors need more information about health insurance. Many of these elderly people knew little about their coverage and eligibility for benefits, how to submit bills or how to collect payments due them, according to McGann.

McGann and Taft initiated a local training program for health insurance counselors, from which this book developed. The training program now is expanding throughout California and other states with the aid of a grant from the Luke B. Hancock Foundation.

Only 38 percent of medical care costs of the elderly are paid for by Medicare, according to the authors, but many seniors have no supplemental insurance to fill in the gaps. Others have too much coverage, duplicating services with unnecessary expense.

"People expect Medicare to cover everything, but it's not a panacea," explained Taft. "We are teaching people to fill in the holes in Medicare coverage with other policies which will maximize their benefits."

Insurance counselors also help seniors collect their benefits, fill out complicated forms and re-file for coverage when mistakenly turned down.

The elderly are particularly vulnerable to the rising costs of health care because many have fixed incomes. The extra burdens of prolonged illness and decreased mobility often add to their difficulties, the authors say.

The authors hope the new manual will encourage the establishment of health insurance counseling programs, and help the 22.9 million people over 65 in the U.S. to be "advocates for change in the field of health care and coverage."

The book was sponsored by a grant from the Administration on Aging in Washington, D.C., through the Council on Aging of Santa Clara County, Inc. It is available in looseleaf format from the Council on Aging of Santa Clara County, 277 W. Hedding, San Jose, CA 95110. The cost is $10.

STANFORD—An international effort of scientific research and drug production is needed to control widespread, communicable diseases such as malaria, schistosomes (blood flukes), and leprosy, says Stanford University pharmacologist Tag Mansour.

As many as 250 million people have malaria, and an equal number are infected with blood flukes, largely in tropical, underdeveloped countries.

Other parasitical infections, including sleeping sickness, Chagas' Disease and leishmania, afflict millions of people, yet very little is being done either to treat or prevent these diseases.

In the United States, for example, less than one percent of the research budget of the National Institutes of Health is provided for tropical diseases, and a similar situation exists in the drug industry.

Why? Because there is little incentive to study diseases which are not a major problem in Western countries, says Mansour, chairman of the pharmacology department at Stanford Medical School.

In addition, economic, political and regulatory problems make it difficult for drug companies to investigate and develop new treatments.

Mansour is participating this week in a conference on drugs for developing countries, sponsored by the Institute of Medicine of the National Academy of Sciences.

The conference, held January 29-31 at the NAS in Washington, D.C., will explore the problems of tropical diseases, and seek solutions to them.

Participants include David Hamburg, president of the Institute of Medicine; Joshua Lederberg, president of Rockefeller University; Donald Kennedy, commissioner of the Food and Drug Administration; Senators Edward Kennedy, Jacob Javits; and Richard S. Schweiker, and several other prominent scientists and leaders in government and industry.

Mansour will address the problem of research to develop new drugs January 31.

"There have been remarkable advances in the fields of biochemistry and molecular biology in the past 25 years," he says, "but the drug treatment of parasitic infections has not kept up."

No effective vaccine exists for any of the major parasitic infections, and there are only a few drugs available for treatment or prevention of these diseases.

Mansour has worked for over 25 years to uncover the unique biochemistry of parasites such as the liver fluke and other flatworms. This knowledge may help researchers develop new and more effective drug treatments.

For instance, "we've found that the ability of the parasitic worm to move about is important for its survival in the body, and that the natural chemical serotonin seems to play a role in the control of movement," he says

"If we can block the action of serotonin, we may be able to interfere with the parasite's ability to move, thereby preventing successful infections."

Mansour says research in this area is slow. His group is one of only a handful conducting the research in the U.S.

Even if research produced an effective anti-fluke agent, regulations, economic and political constraints might hinder its production by drug companies and introduction in countries where it is really needed.

STANFORD—A three-session course on "Growth and Development," for girls 11 to 13 years old will be led by Dr. Paula Duke, a pediatrician at Stanford University School of Medicine, beginning February 6.

The course is designed to help adolescent girls feel more comfortable about discussing changes taking place at puberty.

Topics will include height and weight changes, diets, nutrition, development of secondary sex characteristics, menstruation and acne.

A session to brief parents on the subject matter in the course will take place on Monday, February 5 at 7:30 p.m. in room A335 at Stanford Medical Center.

The girls' sessions will be held on three consecutive Tuesdays, February 6, 13 and 20 between 4:30 and 6:00 p.m. in room C358 at the medical center.

The course is part of a research project being conducted by Dr. Duke. A similar course for adolescent boys will be held at the end of February.

Interested individuals may obtain more information on enrollment by calling Dr. Duke at 497-6891.

City desks: Photo and copies of *Stanford MD* magazine available on request if not included with story.

STANFORD—This is the story of Donald L. Bedney, a black student who had a dream.

Bedney's childhood dream was to become a doctor. But unlike many people of his age, he did not have the early education and encouragement to achieve his goal.

His story is typical of many youths in American society. But you never read about them in supreme court decisions and college affirmative action manuals. These never tell you what it is like to be poor, black and disadvantaged.

As Bedney tells it in the current issue of the Stanford medical alumni magazine, his struggle was like the Greek legend of Sisyphus. He was condemned forever to roll a huge stone up a hill until it reached the top. As the stone rolled back, his work increased.

Bedney's education began in a ramshakled elementary school in Monrovia, CA. In 1934 it was anything but a profitable experience.

"The teachers seemed concerned only with play periods and keeping the pupils amused," he recalls. "At age 14, I had not yet learned to read."

With this background, Bedney failed the first semester of junior high school. He was sent to a retired teacher for tutoring in basic English, writing and arithmetic. He repeated the courses and passed.

"But my early failure represented a psychological setback," says Bedney, "especially in view of my ambition to become a doctor."

Bedney's father did many things to earn a living. He was in the trucking business, dealing in scrap iron. He worked in peach orchards supervising Mexican farm laborers. At one time he operated a used furniture store. Young Bedney in his upbringing worked at numerous jobs.

Bedney married Gloria Marie Tillman of Kansas City, Mo., in 1952. She had an associate arts degree in English.

"Naturally that made me more keenly aware of my lack of a high school education," says Bedney.

He audited courses in Pasadena City College and the University of Southern California, then petitioned City College and was granted a high school diploma.

"I had scotched that Sisyphian stone one more time," says Bedney.

Admitted to La Sierra College at Riverside, Bedney began premed courses in in 1954.

"We now had a young baby, and in my second semester I learned my wife was expecting another child," he says. During their years in La Sierra the Bedneys had four more children. Mounting pressures, family responsibilities again prevented his graduation.

-more-

The stone rolled back.

At the same time his father died. The Bedneys returned to Los Angeles to take over the family car wrecking business. He had to secure other jobs to pursue his ambition while supporting a big family.

So he organized a house cleaning business.

In two years he had saved enough money to go back to school, receiving a bachelor's degree in physical therapy from Loma Linda University.

He worked at Patton State Hospital in San Bernandino when he asked about the possibility of admission to Loma Linda medical school.

"The dean pointed out that I now had a profession, and should be satisfied," Bedney says. "But I insisted one day I would study medicine."

The opportunity came when a friend suggested the Autonomous University of Guadalajara.

The Bedneys made the 1,549-mile trip to Mexico only to learn that the classes were conducted in Spanish.

Bedney who knew a bit of Spanish from childhood associations decided to take a chance. He moved with his family to Guadalajara and began to study medicine.

"Eight months later I was able to understand and speak the language," he says. "The course work was reasonably easy, but money problems began to plague me again.

"My loyal supportive wife and our children had to return to the United States. The cost for our children's private school in Mexico was greater than the cost of medical school.

"The greatest expense was for the apartment, food, transportation and insurance.

"At least once every two months I drove home to visit my family and procure funds to keep myself in school. My wife did all she could to help with expenses working as a secretary in Riverside.

"At the end I had made 44 roundtrips from Guadalajara to Riverside."

But Bedney learned that if he finished his training in Guadalajara, he would have to go to Canada for his internship. Mexico has no reciprocity with U.S. medical schools.

This prospect forced him again to look elsewhere. In 1968 he was driving to San Francisco on Highway 101 when he noticed a sign to Palo Alto. Remembering that he had a friend doing a pathology residency at Stanford University Medical Center, Bedney stopped to visit him.

"I was awed by this outstanding facility," Bedney recalls. "Our setup in Mexico was primitive in comparison."

He talked to Stanford medical school officials and was encouraged to apply. He was admitted in 1969 and was assisted by the loan office of Stanford and scholarships from the Riverside County Medical Society.

Two years later at commencement Donald L. Bedney, M.D. proudly walked down the aisles to receive hid diploma.

Says Bedney: "I remember how I said to myself over and over—in something of a mournful triumph—'I'm a doctor! I'm a doctor!' It was hard to believe that after 18 years I'd finally pushed that Sisyphean stone to the top of the hill."

Bedney is now in general practice in Huntsville, Alabama. He also is an emergency room physician for Redstone Arsenal Army Hospital, and a student health service physician at Oakwood College.

His children are studying to enter health and law careers.

STANFORD—Development of the visual system, how hormones work, some possible clues to treatment of senility, and factors causing arthritis, are among the subjects being studied by young scientists at Stanford University School of Medicine.

Their research is funded by the Biomedical Research Support Grant provided to Stanford by the National Institutes of Health, and administered by a Stanford faculty committee.

The grant helps young scientists to establish research programs in widely varying areas of both basic and clinical research.

The six assistant professors recently awarded one-year grants are Andrei Calin, M.D. (medicine); Thomas B. Horvath, M.D. (psychiatry); Gordon M. Ringold, Ph.D. (pharmacology); Carla Shatz, Ph.D. (neurobiology); Stephen J. Shochat, M.D. (surgery); and James P. Whitlock, Jr., M.D. (pharmacology).

* * * * *

Calin will study Reiter's disease, one of many forms of arthritis which afflict millions of people.

Several years ago, it was discovered that a certain hereditary factor is linked with the development of Reiter's disease, says Calin. But the disease also seems to be triggered by infections with some types of bacteria.

He hopes to determine which varieties of bacteria help cause Reiter's disease, and he will analyze them to discover which components of the cell wall are responsible in triggering the disease.

Horvath will study how a drug affects one aspect of brain function, measured by a brain wave called P300. This wave is believed to indicate the brain's speed in simple decision-making, according to Horvath.

He will measure volunteers' delayed responses to unexpected sounds. Scientists know that delay of the P300 increases as people get older. Also, they have shown that subjects who receive choline, a drug resembling the body's natural neurotransmitter, show significant memory improvement.

Horvath wants to know if choline also helps improve a person's ability to make simple judgements. This could lead one step closer to helping old people or those with memory problems, he says.

Ringold's research is in steroid hormones and the role they play in regulating the characteristics of each cell in the body. He will examine how hormones called glucocorticoids help regulate this task.

Shatz is working on the organization of the visual system—how its complex structure is set up, how cells in the retina make orderly, unscrambled connections with cells in the brain, and what genetic and environmental factors control these processes.

Shochat and his colleague, Dr. Andrew Ford, are interested in a condition of the intestine which develops in many premature babies subjected to extreme stresses such as severe cold, infection, or respiratory distress.

Sometimes these small babies must have portions of the affected intestine surgically removed and it takes months for the remaining intestine to grow back enough to function normally.

Shochat and Ford will study rats to determine the conditions which affect the intestine's rate of growth, including the age at which the surgery is performed and the effects of different methods of feeding following surgery.

In the cells of animals and man, DNA, the genetic material of all living things, is organized with proteins into a complex structure called chromatin.

Whitlock will study how cancer-causing chemicals interact with chromatin. These chemicals are believed to directly modify the chromatin complex, and clues to chromatin structure may come from studying the process.

or John Hargraves 415: 497-5785

STANFORD—At last count an estimated 40,000 Americans who, because of kidney failure, require regular hemodialysis treatments or face certain death.

The physical, emotional and financial facts and problems endured by these men, women and children will be the subject of a comprehensive public seminar on Saturday, Feb. 10, at Stanford University Medical School's Fairchild Auditorium.

The day-long seminar, "What is Hemodialysis?" is being sponsored by the Northern California chapter of the American Association of Nephrology Nurses and technicians and the Kidney Foundation of Northern California.

Hemodialysis, explains seminar coordinator John Hargraves, is more than just the cleansing of the blood by artificial kidney apparatus. For patients needing it, hemodialysis "is a whole way of life."

Hargraves added, "if anyone has a friend, neighbor or relative who is or will be on dialysis, or for those people who simply want to know more about dialysis then this siminar is exactly what they are looking for."

Hargraves, who is chief technician at Stanford's Hemodialysis Center, noted that a wide range of topics involving hemodialysis care will be covered in the seminar. Among these will be federal support and funding, mechanical devices, causes of renal failure, side effects, treatment, options, ultrafiltration and diffusion, and kidney transplantation.

In addition to Hargraves, speakers will include Jan Whitman and Steve Gumina of Stanford; Arlene Sukolsky, regional director of End Stage Renal Disease Network Coordinating Council; Margaret Robinson, in-service coordinator for dialysis at Herrick Hospital in Berkeley; Lee Luckenbill, social worker in the artificial kidney unit at El Camino Hospital in Mountain View; Sandy Wells of the Medical Bureau in San Francisco; Robbie Law of the Artifical Kidney Center at Veterans Administration Medical Center in Palo Alto; and Elaine McCaw, head nurse at the South County Self Care Center in Hayward.

Hemodialysis patients are generally treated three times a week, Hargraves explained, requiring about four hours per session. The treatments, in turn, are expensive, he noted.

For each patient dialyzed in a hospital the cost is approximately $30,000 a year, about 80 percent of which is paid by medicare and the remainder by the patients or their insurance companies. Home dialysis care costs about $10,000, much of which is covered by Medicare.

Through improving medical techniques life expectancy for dialysis patients is becoming markedly better, Hargraves said.

He further noted that similar medical advances have made it possible for young patients to undergo kidney transplants. In Northern California transplants are performed at Pacific Medical Center and the University of California, both in San Francisco, and at the University of California in Davis.

Those interested in the Stanford seminar should call or write the Stanford Hemodialysis Center, Stanford Medical Center, Stanford 94305, (415) 497-5785. Registration deadline is Feb. 4.

STANFORD—Reggie Kriss has lived with cancer for 22 years. "I can't forget I've had it," she says. "I'm always aware that I'm living with something which at any time is capable of destroying me."

Yet, for Kriss this knowledge is not a sentence of death, but an invitation to life.

She is clear-eyed and energetic, and speaks openly about her disease and the meaning she finds in helping other women with breast cancer.

"It took cancer to help me find out my life can mean so much. I have dedication I don't think I would have had before."

For the past three years, Kriss, who is a licensed counselor, has been leading groups of cancer patients in therapy with Stanford psychiatrists Irvin Yalom and David Spiegel.

So far, over 50 women have participated in the groups, which are held in the department of psychiatry at Stanford University School of Medicine.

Kriss finds that she has a special kinship with the women she helps in therapy. They know she understands how they feel, because she has been through it herself.

Cancer struck Kriss not once, but twice. The first lump was discovered in her breast during a trip to England with her family in 1957. The breast was removed and subsequent radiation treatments left her right arm swollen, her hand numb. She was 31 years old, a mother of two children aged four and seven, and she felt very alone.

At that time there were no prostheses or breast reconstructions, and "cancer was something people didn't talk abut." So Kriss kept her cancer a secret, even from her children.

But instead of brooding, Kriss decided to make every minute of her life count. "I was aware that my life was going to be shorter because of the cancer," she says. "As a result, I did more things than I ever thought I could."

When the family returned to the States, Kriss trained for a masters degree and credential in high school counseling, and took a job at a predominantly black high school. It was a "demanding, but very exciting position." Within five years, Kriss had established a college workshop for the students, and was bringing in blacks from a variety of professions to talk about their jobs. Her classes were always crowded, and she still receives letters from some of her students.

Then cancer struck again. A lump was found in the other breast, and a second mastectomy was done.

-more-

Kriss slid into depression. "I had no energy. I felt that my life was over," she says. But she began to talk about her disease to her friends, and revealed for the first time in 14 years that she had had cancer before.

Eventually, she went back to school for a license in marriage and family counseling. During her internship, she took a class in death and dying at Stanford from Dr. Irvin Yalom.

"I had confronted death several times," she says. "I wanted to know more about it so I could deal with it, and use it in a way that would make my life more meaningful."

Yalom asked her to join him in leading a group of women with breast cancer. "At first I was afraid," she said. "My husband, Dr. Joseph Kriss, head of nuclear medicine at Stanford, was concerned that it would be too depressing for me and possibly for him."

But instead, Kriss found the group to be exciting. Here were women sharing feelings they had never revealed to anyone, about their pains, and their fears of being disfigured, dependent, unwanted.

"The most devastating thing to a woman is to have her sexual image damaged," says Kriss. "Cancer patients are terribly afraid of frightening other people. They feel frightened themselves and alone."

Group therapy first shows women that they are not alone, she says. By sharing their feelings and fears, they begin to help each other, and their self-esteem grows. "It's not so bad to need help. After all, each of us is dependent on the other."

In this atmosphere of compassion and warmth, many of the women find they can open up for the first time to their friends and families. Families also meet together, "for they too need to know they are not alone in their experiences."

But the greatest lesson of the therapy is an existential one, says Kriss. "I have learned that one does not confront death until it is imminent. It is like trying to catch the message of a barely audible lecturer; you don't really hear what is being said until you are in the front row."

That confrontation is sudden and traumatic for the patient with cancer, but necessary. It is as if "an invisible screen divides cancer patients from those who are disease-free and unaware of their mortality. Once they realize that, patients are able to break through the barrier, and begin to adjust to a more effective life with themselves and others."

Originally, the groups included only women with breast cancer. They have since been opened to all patients with advanced cancer. For further information about the groups, contact Reggie Kriss, 497-6352.

Group therapy seems to be a formula which works for these patients. For many, including Kriss herself, it is a source of strength and hope. If cancer should strike a third time, "I won't feel alone. I will draw from other patients I've known the strength to help me in my own struggle. Already my life has been richly enhanced simply by associating with these women in the group."

FOR IMMEDIATE RELEASE

STANFORD—

The Bay Area and Boston probably have the highest ratio of physicians to population of any area in the U.S., Acting Dean Lawrence Crowley of the Stanford Medical School told the Faculty Senate Thursday, Jan. 18.

Increased competition for patients may already have led to a decline in personal income for some local physicians, he said. Government unwillingness to support the costs of medical education directly associated with the costs of providing patient care have created a growing financial problem at the School.

Both locally and nationally, improved methods of treatment and closer professional review of medical practice has led to shorter hospital stays. Crowley added. One result is that Santa Clara County now has about 800 unused hospital beds daily.

Advances in medical care itself, slower population growth, and the emergence of "antimedical feelings" among the public also have added to the problems of practitioners.

Both Crowley and Dr. Robert Chase, professor of surgery, criticized the growing reluctance of government to support any part of medical teaching through patient care reimbursement.

Where there once was "a fair amount of piggy-backing of teaching off of research," Crowley said, this has now become a "no-no."

Research support is "flattening" and federal funds for medical training have been eliminated.

Where capitation grants once were used to encourage expansion of M.D. programs, "now we're being decapitated," he quipped.

Simultaneously, government agencies have exerted "very serious cost containment pressures" on patient care, Crowley said.

He emphasized that there is "no inherent, absolute conflict" between research and patient care. In fact, "excellent clinical research and clinical teaching absolutely requires strong patient care."

Charges that Stanford is violating state law concerning the corporate practice of medicine if sustained, could leave the University unable to bill for any professional services rendered patients by its full-time faculty.

"Obviously, that's completely untenable," Crowley said. "It would require a significant organizational change (for Stanford physicians) or a challenge of the decision in court."

While the Medical School faces a potential deficit of $1 to $2 million annually, "we're alive and basically healthy, with a tremendous reservoir of faculty talent," Crowley said. The present "time of troubles" contains within it "seeds for development of an even stronger center" for medical care, teaching, and research.

Two recent surveys have ranked Stanford second only to Harvard nationally in the caliber of medical faculty.

STANFORD—Women who smoke heavily during pregnancy significantly increase the risks of having spontaneous miscarriages and birth defects in their children, according to a report from Stanford University School of Medicine.

In a survey of nearly 28,000 women in the medical profession, miscarriages were found to occur one and a half times as often among smokers, and the rate of birth defects actually doubled in some groups of smoking women compared with their nonsmoking counterparts.

"This is one of the first studies which has demonstrated a statistically significant increase in birth defects in children of women who smoke heavily (a pack or more of cigarettes a day)," said Dr. Byron W. Brown, Jr., professor of biostatistics at the Medical School.

Brown conducted the research with Mr. David U. Himmelberger, of the Stanford Center for Drug Addiction, and Dr. Ellis N. Cohen, professor of anesthesia. Their report was published in the December 1978 issue of the *American Journal of Epidemiology*.

The researchers conducted a mail survey of women anesthesiologists, nurse anesthetists, operating room nurses, techicians, and members of the American Nursing Association.

The women reported about 13,000 pregnancies during the period 1963-1972. Of these, 10,500 had resulted in live births.

Rates of miscarriage and birth defects were greater among smokers in every age group.

Among both smokers and nonsmokers, older women had a greater rate of miscarriage. However, higher rates of birth defects occurred among children of younger women, especially those in their first pregnancy.

This was a surprising finding, said Brown, but it has been confirmed by studies conducted at other centers.

Though it is true that Down's syndrome, or mongolism, occurs more frequently in children born to women over the age of 35, this condition makes up only a small fraction of the possible birth defects, which may include defective hearts, lungs, bones, and intestinal, urinary and nervous disorders.

"It may be that women whose pregnancies result in disastrous births are less likely to try again," said Brown. Therefore, the highest birth defect rate would be expected to occur in the first pregnancy.

Older women who smoked had the highest rates of miscarriage. Children of younger women in their first pregnancy who smoked were at greatest risk of having birth defects.

The research on smoking grew out of a study by the American Society of Anesthesiologists on the effects of trace anesthetic gases on the health of operating room personnel.

This study, reported in 1974, suggested that exposure of anesthesiologists, nurse anesthetists, and technicians to anesthetic gases in the operating room may be responsible for increased incidences of cancer, liver disease, spontaneous miscarriage, and birth defects observed in these groups.

The smoking study provides additional support to these findings, and indicates the risks to operating room exposed women who also smoke.

FOR FURTHER INFORMATION CONTACT: Bill Snyder 415: 497-6911

STANFORD—Aspirin may one day be used to prevent rejection of transplanted organs and arteriosclerosis in humans, according to researchers at Stanford University School of Medicine.

Rejection occurs in two ways. The first involves invasion and destruction of the transplanted tissue by white blood cells.

The second form of rejection is marked by rapid development of arteriosclerosis (hardening of the arteries) in the organ, often within months of transplantation.

Dr. Stuart Jamieson, research fellow in cardiovascular surgery at Stanford, and his colleagues have found that both forms of rejection in rats are associated with the presence of platelets, transparent cells which play a role in coagulation and repair of injured tissue.

The researchers were able to prevent rejection by giving aspirin and other drugs known to lower blood levels of platelets.

Jamieson reported these findings January 15 at the National Science Writer's Forum in Dallas, sponsored by the American Heart Association.

Currently, acute rejection by white blood cells can be prevented by drugs which suppress the body's immune responses. Unfortunately, the drugs also knock out the body's defenses against other foreign materials, including common germs.

The second form of rejection, hardening of the arteries, is more difficult to control. "Accelerated arteriosclerosis is the main cause of death in long-term survivors of heart transplantation," said Jamieson. Six patients at Stanford have had second transplants because of this condition.

The Stanford group studied the development of arteriosclerosis in closely inbred strains of rats which had received transplanted hearts.

They found that platelets began to aggregate on the insides of the blood vessels in the hearts soon after transplantation.

Later, the blood vessel lining was damaged, apparently by the platelets themselves. Other platelets then piled up on the damaged site, eventually clogging the vessel.

The researchers found that they could prevent platelet build-up by giving aspirin and other anti-platelet drugs soon after transplantation.

The drugs also helped prevent early rejection of the hearts by white blood cells.

According to Jamieson, damage done by platelets may leave breaks in blood vessels, through which white blood cells can infiltrate and reject the heart tissue.

By preventing the build-up of platelets, the drugs seemed to protect the blood vessels from invasion by white blood cells.

Jamieson is now testing the drugs in transplanted dogs and monkeys under grants from the American Heart Association and the British Heart Foundation.

TWO STORIES: Dave Fulton, 497-4902 Bob Beyers

FOR IMMEDIATE RELEASE

STANFORD—

Dwain N. Fullerton, director of corporate relations in Stanford's Office of Development, has been named associate vice-president for medical development, a newly created position.

Fullerton's appointment was announced by Dr. Lawrence G. Crowley, acting vice-president for medical affairs, and by Joel P. Smith, the University's vice-president for development.

The appointment, effective Jan. 22, followed a national search and reflects an increased commitment by the University and its Medical Center to a comprehensive development effort for both the School and the Hospital. The Center faces many major capital and programmatic needs which must be addressed in the next several years.

A Stanford alumnus and long-time Palo Alto resident, Fullerton has headed the University's corporate relations program since 1969. During the period there has been a steady growth in gifts from corporations, which now amount to 12% of the University's annual gift totals.

Prior to his corporate position Fullerton worked with the Graduate School of Business as associate director of the International Center for Advancement of Management Education, and as associate dean of a business school in Lima, Peru, modeled after the GSB.

His first fund-raising experience was in Stanford's annual fund, starting in 1960.

Fullerton earned his A.B. from Stanford in 1958 and his MA in 1960. In addition he attended the National University of Chile as a Fulbright scholar.

FOR IMMEDIATE RELEASE

STANFORD—

Psychology Prof. Phil Zimbardo of Stanford will discuss "prisons of the mind" and "the psychology of evil" on the nationally syndicated Phil Donahue show from 11 am to noon Monday, Jan. 22, on KTVU (Channel 2).

The program will be shown in over 70 cities during the next two months.

FOR IMMEDIATE RELEASE
STANFORD—

Stanford, Berkeley, Harvard, and Michigan have the nation's most highly regarded faculties in across-the-board strength, a new national survey indicates.

Involving more than 4,000 faculty at four-year colleges and universities, the survey was conducted by Profs. Everett C. Ladd Jr. of the University of Connecticut and Seymour Martin Lipset of Stanford, both of whom hold appointments at the Hoover Institution.

Their findings are reported in the Jan. 15 *Chronicle of Higher Education.*

Questionnaires distributed in 1977 asked respondents to "name the five departments nationally in your discipline that have the most distinguished faculties," in order of their importance.

Both Stanford and Berkeley were ranked among the top five by 10% or more of the respondents in 17 of the 19 fields covered. Harvard was similarly ranked in 16 fields, Michigan in 15.

They were followed by Yale and Chicago, 12 each; Illinois, 11; Columbia, 10; and Princeton and MIT, 8 each.

(While not directly comparable, a 1969 survey of scholars in 36 graduate fields sponsored by the American Council on Education found Berkeley ranked among the top five in 32, followed by Harvard, 27; Stanford 16; Chicago, 14; Yale, 13; MIT, Michigan, and Princeton, 12 each; and Cal Tech, 11.)

In the 19 fields covered in the latest survey, Harvard was ranked first in seven—biological sciences, chemistry, economics, history, medicine, philosophy, and political science.

Stanford ranked first in three fields—business, education, and psychology—and second in both engineering and medicine. (Several other surveys in recent years have reached similar conclusions.)

Yale led in three disciplines—English, foreign language, and law. Berkeley led in two—physics and the combined field of mathematics and statistics.

Individual leaders in other fields covered by the survey were: Cornell—agriculture and forestry combined; MIT—engineering; Indiana—music; and Chicago—sociology.

Stanford has no program in agriculture or forestry, and was not cited by 10% of the respondents as among the top five in music.

In other fields, when judged by the frequency of being cited among the five best institutions, Stanford ranked as follows:

Biological sciences, fourth behind Harvard, Berkeley, and Wisconsin;

Chemistry, third behind Harvard and Berkeley;

Economics, sixth behind Harvard, MIT, Chicago, Yale, and Berkeley;

Engineering, second behind MIT;

English, sixth behind Yale, Harvard, Berkeley, Chicago, and Princeton;

Foreign languages, eleventh behind Yale, Berkeley, Harvard, Wisconsin, Princeton, Texas, Columbia, Indiana, Michigan, and North Carolina;

History, seventh behind Harvard, Yale, Berkeley, Princeton, Wisconsin, and Michigan;

Law, fourth behind Yale, Harvard, and Chicago;

Mathematics and statistics, fourth behind Berkeley, Princeton, and Harvard;

Philosophy, eleventh behind Harvard, Princeton, Michigan, Pittsburgh, Berkeley, UCLA, Cornell; Yale, Pennsylvania, and Chicago;

Physics, fifth behind Berkeley, Cal Tech, Harvard, and MIT;

Political science, fifth behind Harvard, Yale, Berkeley, and Michigan; and

Sociology, eighth behind Chicago, Berkeley, Harvard, Wisconsin, Michigan, Columbia, and North Carolina.

Copies of a technical report on methods used in the survey are available from Ladd at the Social Science Data Center, University of Connecticut, Storrs, CT 06268.

THE CHRONICLE OF HIGHER EDUCATION January 15, 1979

How Professors Rated Faculties in 19 Fields

Following are ratings of faculties in 19 fields, based on a survey of faculty members conducted in 1977 by Everett Carll Ladd, Jr., and Seymour Martin Lipset. The first column includes all departments that were rated among the top five nationally by at least 10 per cent of the respondents. The second column indicates the percentage of respondents listing the department as being the "best" in the nation.

AGRICULTURE & FORESTRY

	One of the 5 Best	The Best
1. Cornell U.	42%	13%
2. U. of Wisconsin, Madison	38%	10%
3. Iowa State U.	36%	9%
4. Michigan State U.	31%	10%
5. Purdue U.	30%	3%
6. U. of California, Davis	27%	4%
7. U. of California, Berkeley	26%	8%
8. North Carolina State U., Raleigh	23%	7%
9. U. of Illinois, Urbana	23%	5%
10. U. of Minnesota	22%	4%
11. Texas A&M U.	20%	3%
12. Ohio State U.	13%	1%
13. Oregon State U.	12%	4%
14. Colorado State U.	12%	3%
15. U. of Nebraska, Lincoln	12%	3%

BIOLOGICAL SCIENCES

	One of the 5 Best	The Best
1. Harvard U.	54%	24%

STANFORD—Stanford University has received a three-year, $350,000 grant from the Kaiser Family Foundation to develop analytical tools to help solve complex medical problems.

According to Dr. David Eddy, associate professor in the schools of engineering and medicine, and program director, 26 medical, engineering and business students will tackle complicated medical problems such as the importance of annual check-ups and other preventive measures, the use of expensive and risky diagnostic tests, and the preferred therapy for certain diseases.

They will focus both on solving real problems and on developing techniques that can be used to analyze other problems, he said.

Their findings will be submitted to appropriate organizations such as the State Department of Health, the Food and Drug Administration, or the American Hospital Association.

Quantitative techniques have been used for years to help solve problems in other fields, said Eddy, but their use in decision-making in clinical medicine is less well established.

This is due in part to the kind of training physicians traditionally get, and in part to the nature of clinical medicine. For example, in the business world, outcomes can be measured in dollars and cents. But in medicine, qualitative factors, such as how much a procedure decreases pain or improves the patient's ability to work, must also be considered.

Other factors which complicate medical problems include the seriousness of outcomes, such as death and disability, the variability of individual patients, and the rapid rate at which medical technology changes.

"The ultimate objective of the program," said Eddy, "is to improve the quality and lower the cost of medical care by helping physicians in the decision-making process."

STANFORD—Arguments over recombinant DNA research are "sparks from local collisions of deep underlying forces" of science and society, said one speaker at a public forum held January 13 in Fairchild Auditorium at Stanford University School of Medicine.

Dr. Robert Sinsheimer, chancellor of the University of California, Santa Cruz, spoke before several hundred participants in a forum on the public's role in the conduct of scientific research.

The day-long forum focused on research involving gene splicing techniques and recombinant DNA, the subject of controversy among scientists and non-scientists since the early 1970's.

At that time, some scientists expressed concerns over possible dangers arising from widespread use of the techniques. Dr. Ronald Davis, associate professor of biochemistry at Stanford, was one of the first scientists to voice initial concerns.

Speaking at the forum, Davis said "none of the hypothetical hazards has come true, and there are now no known hazards" in recombinant DNA research.

"Everything we do in the test tube happens in nature," he said.

Davis said that guidelines issued by the National Institutes of Health regulating federally funded recombinant DNA research have been "a disaster" and have delayed progress in this area.

The guidelines have forbidden use of newer and possibly safer methods and have hampered progress in risk assessment experiments, Davis claimed.

"But the real disaster is that they have demoralized young scientists," he said.

Among the conjectured biological hazards of recombinant DNA work, Sinsheimer cited the accidental escape of novel organisms into the environment and the emergence of resistant strains of bacteria.

But other types of hazards must be acknowledged, he said.

"The potential long-term ecological, social and moral hazards of new technology can't be dismissed," he declared, adding that scientists have been reluctant to address these issues.

– more –

The recombinant DNA debate "illustrates our lack of means to address such problems," Sinsheimer said, agreeing that the NIH guidelines have not been a good solution.

Sinsheimer suggested that a "visible platform close to the centers of political power," such as a presidential commission, is needed to deal with these matters.

Burke Zimmerman, science consultant in the U.S. House of Representatives, suggested that "the way the issue of recombinant DNA was introduced to the public may have created polarization."

"The debate got out of hand during the inital stages and was characterized by fear on both sides," he said.

Ronald Cape, chairman of the board of CETUS corporation in Berkeley, said future applications of recombinant DNA technology might include production of human insulin, interferon (an anti-virus and possible anti-cancer agent), and antibodies to fight specific diseases. He also hinted at the possibility of future agricultural and energy applications.

But public participation in the uses of this new technology is desirable, said Richard Knox, medical editor of the *Boston Globe*. "The public wants to accompany scientists down the road," he said.

Following the forum, a group of participants passed a resolution to send a delegation to the California state legislature. The group plans to advocate specific rules in choosing public members of institutional biosafety committees which oversee recombinant DNA research at institutions receiving federal funding.

New NIH guidelines on recombinant DNA research took effect January 2 of this year. The new guidelines are less stringent than previous regulations.

But the revised guidelines call for twenty percent of the members of institutional biosafety committees to "represent the interest of the surrounding community with respect to health and protection of the environment."

The guidelines do not specify how such members are to be chosen.

STANFORD[8]Stanford supports legislation to clarify the manner in which faculty physicians in medical schools bill their patients, Dr. Lawrence G. Crowley, acting vice-president and dean of the Stanford University School of Medicine, said Monday, Jan. 15.

In testimony before the State Assembly Committee on Health, Crowley said that direct clinical care to patients is "an obvious and necessary part"of the process of teaching medical students, interns and residents.

Faculty physicians provide medical care to patients, he said. A system of charging for such services has been in existence in all of the medical schools of California and the nation in one form or another.

"No medical school in the country provides, or could provide these services free of charge," he said.

The Committee on Health held a hearing in Sacramento to determine if California law dealing with the corporate practice of medicine should be amended to specifically authorize physicians on medical school faculties to charge professional fees.

Scheduled to testify at today's hearing were also represehtatives from the University of California, University of Southern California, officials from the State Department of Health, the Board of Medical Quality Assurance, and others.

There is a difference of opinion whether the present law which prohibits the corporate practice of medicine applies or was intended to apply to medical schools. Assembly Bill 19 would clarify the question.

The problem emerged as a public issue because of complaints filed by the Union of American Physicians and Dr. Eugene Dong, Jr., a Stanford associate professor of cardiovascular surgery.

The complaints have alleged that Stanford is engaged in the corporate practice of medicine by having salaried faculty physicians who charge fees and turn them over to the medical school. They claim that Section 2008 of the California Business and Professions Code prohibits physicians who are employed by unlicensed corporate entities to charge fees for their services.

In addition, they have alleged the system leads to "double billing," and inferior patient care.

Their complaints are now under investigation by the Board of Medical Quality Assurance and Medi-Cal.

- more -

Crowley said Stanford is neither in violation of the spirit or letter of the law.

At Stanford it is the individual physician who exercises the discretion to charge or not charge a professional fee, not the institution, he explained.

"The corporate interference in the practice of medicine through the profit incentive which (the law) intended to prevent is simply not present in Stanford's system," Crowley said.

Crowley termed the allegations that Stanford provides inferior patient care as "simply not true."

He explained that 28,000 patients are admitted annually to Stanford University Hospital, and there are more than 134,000 visits in the clinics, and 29,000 emergency visits.

"Isolated cases in which patients are not satisfied with some aspect of their care are bound to exist in any facility that treats as many patients as Stanford," he said.

"But Stanford's reputation for providing excellent care and our record of patient satisfaction is at least the equal of any other medical center of its size in the nation," he said.

Stanford, Crowley said, serves as a major referral center for patients with rare and difficult medical problems from thoughout the United States.

That other physicians refer so many patients to Stanford is an important testimony to the high esteem they hold regarding Stanford's services, he said.

Commenting on the billing allegations, Crowley said every aspect of Stanford's billing system since the beginning of Medicare and Medi-Cal was approved annually by the appropriate agencies and auditors.

"Nothing has been hidden," he said. "The problems with which we are now dealing are based on practices that have been on the record and approved at every stage.

"Nevertheless, these allegations are serious and they are being treated seriously. Stanford is making every effort to insure that they are fully investigated.

"It is in our best interest to see that the allegations, which involve extremely complex regulatory issues, are resolved."

Crowley said faculty physicians now must comply with many legal requirements before a fee is charged.

These include the requirements of Medicare, Medi-Cal, the Board of Medical Quality Assurance, and the Department of Consumer Affairs.

"If you act favorably on this legislation," Crowley said, "you will in no way have changed these legal requirements."

The proposed change, he added, is also so narrowly written to include only physicians on the faculties of nonprofit university medical schools which operate clinics for the purposes of medical education.

STANFORD—Dr. Eugene M. Bricker, emeritus professor of clinical surgery at Washington University in St. Louis, will present the ninth *Louis and Dorothy Kovitz* visiting professorship lecture at Stanford University School of Medicine Friday, January 19.

Bricker will speak at 4 p.m. in Room M-106 of the Medical School on the role of radical surgery for pelvic cancer.

Physicians and other health professionals in the community are invited to attend.

Bricker has been active in developing surgical treatments for cancer since the 1940s. In particular, he is well known for radical, or extensive surgery to control cancers of the pelvic region.

In addition to his position at Washington University, Bricker is associate director of surgery at Ellis Fischel State Cancer Hospital in Columbia, Missouri.

He received his medical doctorate from Washington University School of Medicine in 1934, and holds several awards, including the Amory Prize from the American Academy of Science, and the Ferdinand C. Valentine Medal and Award from the New York Academy of Medicine.

He has authored or edited over 40 publications, including 10 books.

The Kovitz lectureship was established in 1969 by Dr. and Mrs. Kovitz of Los Altos to bring outstanding lecturers in medicine and surgery to the Medical Center.

STANFORD—Nobel laureate William N. Lipscomb of Harvard University will present the sixth annual Linus Pauling lecture at Stanford University School of Medicine Wednesday, January 17.

The lecture is entitled "How Do Enzymes Work?" and is open to the public. It will be held at 4 p.m. in the Medical School's Sherman Fairchild Auditorium.

Lipscomb, Lawrence Professor of Chemistry at Harvard, is a well-known physical chemist, who has determined the chemical structure of boron hydrides and two enzymes. The hydride work earned him a Nobel prize in 1976.

He studied under Linus Pauling while at the California Institute of Technology, and received his Ph.D. in chemistry there in 1946. Later, he taught at the University of Minnesota for several years before coming to Harvard in 1959.

The Pauling lectures were established in 1973 to honor professor Pauling, who retired from Stanford that year. Sponsored by the Departments of Biochemistry, Biology, and Chemistry, and by the Stanford Magnetic Resonance Laboratory, the lectures were designed to "bring to Stanford distinguished speakers in the fields of molecular biology and molecular pharmacology."

STANFORD—Stanford University's chimpanzees were moved Thursday, January 11 to their new home at the University of Texas in Austin.

Their departure from Stanford brings to a close four years of behavioral studies which once included the resources of internationally-known ethologist Jane Goodall.

The chimpanzees will be kept as a group for breeding and behavioral studies at the Texas facility under a grant from the National Institutes of Health. Dr. Mike Keeling, a veterinarian, directs the facility.

According to Dr. Seymour Levine, director of the Stanford Outdoor Primate Facility which housed the chimpanzees, this is the only group of chimpanzees in the United States used primarily for breeding purposes.

Breeding chimpanzees in captivity is important, not only for the behavioral knowledge which can be obtained from one of humankind's closest relatives, but because the supply of research animals from their native habitats has been sharply curtailed in recent years.

The Stanford facility was established in 1974 to permit behavioral and biological studies of chimpanzees in conjunction with similar studies at the Gombe Stream Research Center in Tanzania by Dr. Jane Goodall.

Goodall served as co-director of the facility with Dr. David Hamburg, former chairman of the Stanford psychiatry department and currently president of the Institute of Medicine of the National Academy of Sciences.

The facility also provided training for students who wished to do research at the Africa field station.

But in May 1975, four of the Stanford personnel at the station were kidnapped by Zaire guerrillas. Although they were later released unharmed, the incident resulted in the termination of the association between the station and Stanford.

The loss of the Gombe center prevented researchers at Stanford from comparing the behavior of chimpanzees in captivity with those in the wild.

In addition, difficulties in obtaining funds for the research and problems in handling the animals led the researchers to consider closing the program.

"Although we have made considerable progress, and have produced data that are interesting in terms of understanding chimpanzee behavior, we believe that in the future the program will have diminishing returns," said Levine, in September 1978.

It has been recommended that the primate facility be used to breed and study rhesus macaques, which breed more quickly than chimpanzees and are more suitable for biobehavioral research.

CITY DESKS: Photos available on request if not included with story.

STANFORD--A young Modesto housewife is alive and well thanks to a new emergency transport system operated by Stanford University Hospital.

Mrs. Debbie Avrett had checked into Modesto City Hospital for a Caesarean delivery. When she awoke in the recovery room, her new daughter was brought in so she could see her.

"Suddenly I started choking and couldn't breathe," she recalled. "That's all I remember."

Mrs. Avrett's physician phoned Stanford for assistance. A special medical team trained in emergency transport procedures was dispatched in a specially-equipped air ambulance.

Within a few hours, she was flown to Stanford where more intensive care could be provided.

"Mrs. Avrett had a blood clot in her lung which led to respiratory arrest and heart failure," explained Dr. Myer Rosenthal, director of intensive care medicine at Stanford. "We were able to provide the intensive monitoring she needed, as well as fresh personnel, around the clock."

Now, the young woman has recovered and is home, reunited with her husband, her parents and her new daughter.

Mrs. Avrett was the first patient in a new program of ground and air ambulance transportation now bringing critically ill patients to Stanford University Hospital.

The new "adult transport service" was created to lessen the dangers of transport for patients whose care would benefit from a move to Stanford, according to Rosenthal.

"Not every hospital has the staff or equipment to deal with critically ill patients, particularly with the increasing sophistication and cost associated with such care," he explained.

"We hope that this program will be beneficial to patients in this area as well as in adjacent counties," he added.

Stanford Hospital currently receives one or two patients each week from other medical facilities although not all of these patients are critically ill, Rosenthal explained.

"The patients we receive through the new service are severely ill patients that physicians have been reluctant to transport," he noted.

- more -

Hospital staff maintain close communication with doctors concerning their patients, according to Rosenthal, and the transition from the community to Stanford, and back again, proceeds without interruption of care.

Rosenthal named some specific benefits the service offers:

. availability of subspecialists in every area of medicine on a 24-hour basis

. monitoring and cardiac support with the most sophisticated equipment available

. hemodialysis for critically ill patients

. a medical team of doctors, interns, residents and nurses, available on a 24-hour basis.

"These days there are controls over facilities expansion, and not every hospital can be all things to all patients," Rosenthal said.

By decreasing the need for duplication of expensive equipment and services, Rosenthal thinks that the ultimate savings to the region might be considerable.

The service works this way. A physician requesting transport phones a dispatch center at Stanford. The dispatcher contacts a physician from Stanford's intensive care unit or emergency department, who acts as coordinator.

The decision to transport a patient is made only after the patient (or the patient's family) consents to the move, and Rosenthal said that medical insurance covers the expense.

The transport team assumes full responsibility for the patient's care as soon as they arrive at the patient's bedside. Transport is by ground ambulance, if within 50-75 miles of Stanford, or by air and ground ambulance if the distance to Stanford is greater.

One member of each team is a physician, and trained nurses from the intensive care and emergency units at Stanford Hospital also participate. Occasionally, a monitor technician accompanies the team.

Standard equipment includes a respirator, sophisticated heart monitoring tools, and drugs to handle any type of medical crisis, said Rosenthal.

A similar service for newborn and pediatric patients has been in operation at Stanford for several years.

The new program, which has been in planning for three years, will be reviewed regularly, according to Rosenthal. Purchase of special transport vehicles may be considered in the future, he said.

Such vehicles might enable the hospital to offer an emergency rescue service with "management and transport of critically ill or injured patients directly from the scene of accidents," he added.

There are a few private air transport services already in operation, but not many are hospital-based, said Rosenthal. A rescue air transport run by the state has been operating for several years in Maryland, he noted.

STANFORD—

Two young faculty physicians at Stanford University School of Medicine have been awarded a two-year grant for $150,543 from the American Cancer Society to study the effects of radiation and drug therapy on kidney growth, structure and function.

Dr. Sarah Donaldson, associate professor of radiology and pediatric radiation therapist, and Dr. Peter Moskowitz, assistant professor of radiology and pediatric diagnostic radiologist, became interested in this problem several years ago when they noted x-ray findings suggesting abnormal kidney growth in children who had been successfully treated for Wilms' tumor.

A cancer of the kidney which occurs in young children, Wilms' tumor is the most common abdominal tumor, accounting for about seven percent of all malignancies seen in children, according to Donaldson.

"Fortunately, we can cure over 80 percent of all Wilms' tumor cases," she added. The treatment involves surgical removal of the diseased kidney, followed by radiation therapy and chemotherapy with a combination of two or three drugs.

Normally, when a kidney is removed, the body's other kidney grows in size in order to compensate for the functions originally accomplished by the two kidneys.

Moskowitz found that compensatory growth did not occur in the remaining kidneys of several children treated for Wilms' tumor with abdominal radiation and chemotherapeutic drugs.

Finding little information available on the effects of radiation and drug therapy on normal and compensatory kidney growth and function, Moskowitz and Donaldson decided to pursue their observations experimentally.

"This is the way a lot of medical knowledge is acquired," they noted. "A clinical observation is made, and then we go to the laboratory to learn more about it."

"The current drugs effective against Wilms' tumor include vincristine, actinomycin D and adriamycin, which are used with radiation therapy," Moskowitz explained.

Preliminary studies, funded by the Stanford Research Development Fund, Adria Labs, and the American Cancer Society, California Division, showed that, in mice, radiation alone and each of the drugs alone, inhibits compensatory kidney growth and overall body growth. Kidney function was not examined, Moskowitz said.

Their new study will examine the effects of these drugs, alone and in combination with radiation therapy, on kidney growth, structure and function in baby mice, a good model of the mammalian system, according to Moskowitz.

Normal kidney growth will be studied in mice with both kidneys intact, and compensatory growth in mice which have had one kidney removed, mimicking the type of treatment used for Wilms' tumor in humans.

"As cancer therapy becomes more aggressive, there is more awareness of the complications to normal tissues," explained Moskowitz. "Normal tissue injury develops slowly. Although such therapy may not be harmful during the treatment period, will children receiving therapy develop other kidney troubles later in life?"

"Since this is a highly curable cancer in humans, there will be many long term survivors," Donaldson said. "All anti-cancer therapy has side effects, and the complications of treatment must be recognized as well as those of the disease," she added.

"These studies may be applicable to other conditions in which combination chemotherapy and abdominal radiation therapy is used, such as in some other abdominal tumors," Donaldson said.

CITY DESKS: The following is an announcement of a public forum on recombinant DNA to be held at Stanford on January 13, 1979. On the day of the forum, interviews with the speakers may be arranged by telephoning (415) 497-7264.

STANFORD—A public forum on recombinant DNA research and the public's emerging role in policy decisions governing scientific research will be held January 13 at Stanford University School of Medicine.

The forum will take place in Fairchild Auditorium from 10 a.m. to 5 p.m., with a program of speakers in the morning and informal workshops in the afternoon.

Recombinant DNA techniques enable researchers to manipulate the genetic material basic to life, splicing genes from one species to another.

The benefits and risks of such research have been the subject of much debate among scientists, many of whom now feel the risks have been exaggerated.

As a result, revised guidelines regulating federally funded research were recently issued by the Department of Health, Education and Welfare.

The new guidelines also require increased public participation in decisions regarding the conduct of recombinant DNA research.

Local institutional biosafety committees must now select at least 20 percent of their members from the public.

Compliance with the revised membership guidelines is required by January 31 of this year.

One focus of the forum will be the role of the public on such committees.

Other issues to be addressed at the forum include the relationship of federal regulations and legislation to local control of research, and the benefits and risks associated with recombinant DNA research.

Speakers will include Ronald Cape, chairman of the board, CETUS corporation; Dr. Ronald Davis, associate professor of biochemistry at Stanford; Dr. Robert Sinsheimer, chancellor of the University of California, Santa Cruz; and Burke Zimmerman, science consultant in the U.S. House of Representatives, who contributed to the new guideline formation.

Among the topics of the workshops are the citizen's role in science policy, approaches to regulation, worker safety and training, and science policy issues for educators.

Many community organizations are co-sponsors of the event, which is funded by the California Council for the Humanities and Public Policy.

Attendance is free, and the public is invited to participate.

For more information, or for preregistration materials, call the Stanford University Division of Health Services Research at (415) 497-6426.

STANFORD—Breast reconstruction will be the subject of the first in a series of free public lectures on women's health beginning Tuesday, January 9 at Stanford University School of Medicine.

Nine lectures will be presented each Tuesday at noon in Room M104 of the medical school. The annual series is sponsored by the Department of Family, Community and Preventive Medicine.

Dr. Netta Grandstaff, senior research associate in the department, will give the first lecture. Grandstaff is well-known locally for her work with breast cancer patients, and has directed workshops on breast reconstruction for several years.

The second lecture, on January 16, is entitled "Teenage Pregnancies: Current Status and Birth Control." The speaker will be Dr. Vickie Hufnagel, of the obstetrics and gynecology department of Los Angeles' Cedar Sinai Hospital.

Future topics include: "New-Old Techniques in Childbirth"; "DES Daughters—Where are they"; "Menopause and Depression"; "Female Sexuality—Past, Present, and Future"; "Legal and Moral Issues of Informed Consent"; "Family Planning—A Cross Cultural Study"; and "Health and Socially Related Risk Factors Among Older Women."

STANFORD—Stanford University medical students are performing less well on the National Board Examinations compared with previous years, according to a letter distributed Monday, Feb. 26, to the faculty and students of the Stanford University School of Medicine.

The letter, issued by Dr. John P. Steward, associate dean for student affairs, states that 37 percent of the medical students who took Part I of the examination in 1978 failed all or part of it. By comparison the failure rate on Part I for 1977 was 27 percent, and for 1971 was 12 percent.

Steward said the recent pronounced downward trend in student performance on Part I began in 1977 and is a phenomenon also noted in other medical schools with which Stanford frequently compares itself.

"The reasons for this decline are neither simple or obvious," he said. "But an analysis of possible reasons is essential."

Passing the National Board Examinations is a requirement for the medical degree at Stanford. The tests, which can be retaken, are administered in June and September by the National Board of Medical Examiners. Part I tests students for their knowledge in the basic sciences, and Part II in clinical sciences.

Steward said the performance on Part II of the Stanford graduates has been relatively constant since 1974, but was higher prior to that year.

For years when the National Board of Medical Examiners ranked medical schools based on the performance of their students, Stanford frequently placed among the top six schools in the U.S. Such rankings are no longer prepared by the Board of Medical Examiners, Steward noted.

The 1978 mean score for Stanford medical students is equivalent to the 54th percentile in basic sciences and 63rd percentile in clinical sciences for the appropriate national standard reference group.

Steward said his office released these data because it is important that they be considered in the deliberatons of the Medical School's faculty senate. A faculty senate committee chaired by Dr. Ruth T. Gross, professor of pediatrics, is currently making recommendations for improvement of the evaluation of student performance.

In a preliminary report to the senate Friday, Dr. Gross stated the majority of the faculty were dissatisfied with the present system of evaluating student performance in the Medical School.

"One fourth of the faculty think students now enter their clinical clerkships with basic science preparation below standard and also that Stanford is graduating a significant number of students whose knowledge is below acceptable standards," she said.

Dr. Gross outlined several remedies. They ranged from improved counseling of students with marginal performance, better procedures to inform them of their progress, to dropping under certain conditions the failing students from the M.D. program.

The Gross committee report is expected to be published in a few weeks.

STANFORD—"Mars in 3-D," a dramatic movie based on image data taken by the Viking Mission to Mars will be screened twice on Thursday, March 1, at 7 and 9 p.m. in Fairchild Auditorium at Stanford University School of Medicine.

The movie is open to the public at no charge. As the title indicates the movie is in 3-D and the audience will be given special glasses to get the full effect.

Subtitled "Images from the Viking Mission," the movie was developed by Dr. Elliot C. Levinthal, adjunct professor of genetics at Stanford, using advanced computer techniques. It is complete with a stereo sound track of computer-generated music composed by Michael McNabb and William Schottstaedt of the Center for Computer Research in Music and Acoustics at Stanford.

"Mars in 3-D" was made possible because both the Viking orbiter and two landers provided views from cameras in different positions. The movie is basically presented in three parts—scenes from the orbiter, the science test lander, and scenes of the Martian surface.

According to Levinthal, "ridges, outcrops and eroded drifts of the Lander One terrain are clearly shown. The closing scenes show the rock types and troughs that surround Lander Two."

In the film canyons the size of the Grand Canyon are shown in full relief while surface features on the ground near the landers are dramatically shown into the foreground. Many background crater rims and rocks are seen as clearly etched topographical features.

Levinthal produced the film and Kenneth L. Jones, working at the Jet Propulsion Laboratory at California Institute of Technology (Cal Tech), directed it. Uri Geva, a graduate student in the communications Department at Stanford, was film advisor and editor.

Commissioned by the National Aeronatics and Space Administration (NASA) as part of the Viking project, the movie was shown last month at the Second International Colloquium on Mars held at Cal Tech in Pasadena.

STANFORD—Dr. Orland A. Soave, director of the division of laboratory animal medicine at Stanford University School of Medicine, has announced his retirement at the end of this month.

He will be succeeded by Dr. James H. Dewson, III, who will serve in an acting capacity while a search for a new permanent director is conducted.

Dewson is an associate professor of hearing and speech sciences in the Department of Surgery. He is currently serving a term as chairman of the university-wide Administrative Panel for Laboratory Animal Care.

As director of the medical school's animal facilities, Soave has been responsible for supervising the care of animals used for teaching and research.

"In the course of his 19 years of dedicated service to Stanford Dr. Soave has been responsible for setting up professional standards for laboratory animal care facilities throughout the nation," said Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the medical school.

Soave was a member of the Animal Care Panel in the early sixties commissioned by the National Institutes of Health to develop standards for animal care and management in the nation's biomedical research facilities.

The standards led to improvements in the training of qualified personnel to supervise animal facilities, and development of proper housing for laboratory animals.

Soave came to Stanford in 1960 from the State Department of Public Health at Berkeley. He is a specialist in veterinary medicine and viral diseases in animals, and a clinical associate professor in the Department of Medical Microbiology.

He has served as consultant in laboratory animal medicine for the Pan American Health Organization, the National Aeronautics and Space Administration, and as editor of the Journal of Laboratory Animal Care.

STANFORD—"The Coming of Age," a series of public talks by Stanford physicians on the physical and emotional aspects of growing older, will be presented on three successive Wednesdays beginning Feb. 28 at Stanford University School of Medicine.

Among the six lecturers will be Dr. Russel V. Lee, clinical professor of medicine, emeritus, at Stanford, and and founder of the Palo Alto Medical Clinic.

The lectures are part of the medical school's Progress in Medicine Series. Each is free and begins at 7:30 p.m. in the school's Sherman Fairchild Auditorium.

The lectures are:

• Feb. 28, "The Body in Which We Journey," a discussion of the biology of aging and on current research at Stanford on the aging process by Drs. Lawrence M. Crapo and Gerald Reaven. Crapo is assistant professor of medicine in the division of Gerontology, and Reaven is profesor of medicine, head of the Gerontology Division, and director of the Geriatric Research, Education and Clinical Center (GRECC) at Veterans Administration Center in Palo Alto.

• March 7, "Aches and Pains," or what happens to the bones and joints in humans as they grow older, by Drs. Thomas B. Okarma and Robert A. Marcus. Okarma is staff physician in gerontology, while Marcus is assistant professor of medicine in gerontology.

• March 14,

"Growing Old Gracefully," and the experiences of age in sexuality, moods and other emotions, by Dr. Leo Hollister and Dr. Lee. Hollister is professor of medicine, psychiatry and the pharmacology, and director of psychopharmacology research at V.A.

The Progress in Medicine lectures are presented by the dean and faculty of Stanford Medical School and by the Medical Center Council. This particular series is being cosponsored by V.A. in Palo Alto, which is associated with the medical school.

ADVANCE FOR RELEASE TUESDAY, FEBRUARY 20, 1979

STANFORD—Health of children and adolescents and training of pediatricians to deal with children's common medical problems will be the focus of a $842,604 grant to Stanford University from The Robert Wood Johnson Foundation.

Stanford was one of six institutions selected by the foundation to receive grants totaling $4.8 million, it was announced Tuesday, February 20. Six-year training and research programs will be established at the institutions, with funding already awarded for the first four years.

In announcing the awards, Robert Wood Johnson Foundation president, Dr. David E. Rogers said, "We hope the program will catalyze major changes in the field, and, in the final analysis, improve the health of children in this country. It is a particularly important goal to stress in this Year of the Child."

According to Dr. Ruth T. Gross, professor of pediatrics and director of the new program at Stanford, there is a need for qualified teachers and faculty in general pediatrics, an area which has been neglected in medical education.

"There is now universal recognition that pediatrics extends far beyond the hospital-based practice where most training occurs," she said.

Young pediatricians become familiar with the rare and highly complicated diseases seen in hospitals, but are not skilled in handling the more common problems of children and adolescents seen in general practice. There is a need for faculty members and teachers with expertise in this area, she explained.

With the help of the grant, training for pediatricians planning to enter academic medicine will be expanded in the department of pediatrics at Stanford, to include two fellows each year in a two-year training program. The fellows will participate in patient care programs, coursework, and in research projects.

According to Gross, research and training opportunities will be broad. Among the faculty already in the program are Dr. Iris Litt, associate professor of pediatrics and director of adolescent medicine, and Dr. Thomas F. Anders, associate professor of psychiatry and pediatrics and director of child psychiatry.

Other pediatric specialties in the department, the Boys Town Center for the study of youth development at Stanford, and the Palo Alto School District will also be involved.

Examples of some areas of research are the effects of early and late physical maturation upon achievement in adolescence, and adolescents' compliance with medication for such problems as acne, neurological disorders and birth control.

By emphasizing research and training of new faculty members, medical education will be better equipped to train future physicians to handle everyday health problems of children and youth, according to Gross.

The other five institutions receiving funds are Duke University, The Johns Hopkins University, Medical Associates Research and Education Foundation (the University of Pennsylvania, Children's Hospital of Philadelphia), the University of Rochester, and Yale University.

The Robert Wood Johnson Foundation, based in Princeton, New Jersey, supports projects aimed at improving access to general medical care services.

STANFORD—Impotence. The word conjures up feelings of guilt and shame, yet it is a major medical problem, afflicting an estimated 10 percent of the male population.

Today there are therapies and treatments available to the impotent man, including biofeedback and surgically implanted devices which simulate erection.

The majority of impotence (80-90 percent) results from psychological and emotional problems, according to Dr. Alan Brauer, director of the Stress Reduction Clinic at Stanford University School of Medicine.

Often, men become impotent because of stress, or problems in their relationships with wives or girl friends.

Behavior therapies and other forms of counseling which include the partner, and biofeedback, can be effective in removing the source of impotence, said Brauer.

Biofeedback teaches patients to relax by providing visual and audible signals about heart rate, blood pressure, muscle tension, and temperature.

By relaxing, patients reduce the "stress and anxiety that have multiple effects on all body systems," he said.

For the highly motivated patient, psychological treatment is successful 60-75 percent of the time.

However, treatment is less effective if the emotional problems are deep-seated, such as a life-long depression, or hatred of women going back to early childhood.

Deep-seated emotional problems can cause impotence as complete as that resulting from diabetes, stroke, neurological disease; excessive drug or alcohol use, or old age.

The solution in these cases is not psychotherapy, but surgery, to implant devices which simulate erection.

At Stanford, Dr. Robert Kessler of the Division of Urology has implanted about 100 of these devices since 1975.

Most of his patients have impotence resulting from disease, but one quarter of them have been referred by psychiatrists after treatment of their emotional problems failed.

Kessler implants two types of devices. One consists of two rods of silicone (a plastic material not rejected by the body) which are inserted in the penis and hold it erect.

The other is an inflatable device consisting of two silicone tubes placed in the penis and a small pump in the scrotum. By squeezing the pump, patients can draw fluid from a reservoir fitted under the abdominal muscles into the tubes, causing erection.

This device, developed in 1972 by Dr. Brantly Scott of Baylor School of Medicine, simulates erection more naturally, and eliminates erosion of the penile tissue which can complicate insertion of the rod device.

Kessler most often implants the inflatable device, with only minor complications, such as leakage of fluid.

Completely implantable, both devices can make patients' lives more normal. Unless the ejaculatory function has also been damaged by disease, they enable previously impotent men to produce children.

"For the 35-year-old man with diabetes, impotence is a major tragedy," said Kessler. "No longer is it something to be ashamed of."

As a result, more men are bringing their problems to doctors. In addition, most insurance companies now provide coverage for the cost of the device and surgery.

STANFORD—Stanford University President Richard W. Lyman announced Thursday, Feb. 15 that he will separate the position of Vice President for Medical Affairs and Dean of the School of Medicine.

Lyman made the announcement in a letter to the committee searching for a successor to Dr. Clayton Rich who resigned in January. Rich held both administrative positions.

"I am asking you to search for a Vice President for Medical affairs at a time when it is increasingly clear that the incumbent will have different responsibilities from the last two holders," Lyman wrote.

"Specifically, we are moving toward a greater degree of de facto separation between the Hospital and the Medical School," he continued. "To put it somewhat differently, there are compelling reasons to believe that both entities will fare better if each has strong, independent leadership."

Lyman said such a leadership will consist of a Dean for the Medical School to whom (academic) departments will report, and a director for the Hospital whose authority will be independent of the Dean's.

"Both of these persons will report to the Vice President for Medical affairs, who will need to have substantial management abilities as well as keen sensitivity to issues of biomedical policy, federal, state and local, and the capacity to define and articulate the institution's positon on them," Lyman said.

"Inevitably, he added, "the precise duties of the position will be defined in part by the qualities of the individual who takes it."

Lyman noted that "this is an important time in the history of the Stanford Medical Center.

"Every university medical center in the country is actually or potentially at risk because of the uncertainties afflicting national policies with respect to medical education, research, and health care."

Lyman's letter constitutes the formal charge to the search committee whose membership was announced last week.

The committee is headed by Dr. Thomas C. Merigan, professor of medicine and head of the division of infectious disease in the Medical School.

STANFORD—Biologists at Stanford University have used for the first time a high energy physics instrument to measure the movements of proteins and obtain a split second picture of molecules in motion.

The successful demonstration was carried out by scientists from the Stanford School of Medicine working in the Synchrotron Radiation Laboratory (SSRL) of the Stanford Linear Accelerator Center.

Using extremely brief light pulses to "freeze" protein movements in the same way a strobe light stops the motions of dancers, the scientists have demonstrated successfully that proteins change shape in less than a billionth of a second.

The use of the instrument in biological research is important, according to the scientists, because flexibility of proteins is vital in their ability to perform many biological functions.

Some protein motion, however, occurs over tiny moments of time in the realm of billionths of seconds and until now, such rapid movements had not been measured.

Dr. Lubert Stryer, chairman of the department of structural biology in the Sherman Fairchild Center at Stanford, Dr. Ian Munro of Daresbury Laboratory in England, and Dr. Israel Pecht of the Weizmann Institute in Israel, reported their research in an article in the January issue of the *Proceedings of the National Academy of Sciences*.

Taking advantage of the storage ring for electrons at SSRL, where electrons whirl in a circular orbit at the speed of light, the scientists obtained pulsed light, or synchrotron radiation, in bursts of extremely short duration.

When these pulses of light hit specific amino acids (the chemical "building blocks" of proteins) within the proteins being examined, fluorescent radiation was observed. The patterns of radiation were analyzed for evidence of amino acid motion independent of the rest of the protein. Such rapid flexing motions had been predicted theoretically for many proteins but never observed before.

According to Stryer, the biological significance of these rapid movements is not understood in detail, but he believes they may trigger certain cell responses to stimuli such as light and hormones.

For instance, understanding these protein motions may give clues to how the body's immune system successfully combats infections.

White cells, which produce antibodies in the immune system, are triggered by certain foreign chemicals called antigens. Protein receptors on the surface of the white cells detect the presence of antigens, and motion of these receptor proteins may be critical for triggering the antibody production, he suggested.

The proteins studied thus far have been serum albumin, a blood protein which scavenges waste products in the body; azurin, a bacterial protein with a "fluid-like" central structure which undergoes large changes of shape in time periods of billionths of seconds; and myelin, a flexible protein found in nerves.

The research was supported by a grant from the National Institute of General Medical Sciences, and the National Science Foundation which supports SSRL.

STANFORD—An eye test, developed by ophthalmologists at Stanford University School of Medicine, was given recently to television viewers in their homes in Columbus, Ohio.

Subscribers to the QUBE Cable TV station took the test on February 6 and 7, and responded through computer consoles attached to their sets.

Ophthalmologists at Ohio State University will now clinically examine those who failed the test, and a certain proportion of those who passed, to determine how accurate the TV test is in screening for vision problems.

"This is the first time medical testing has been attempted on television with audience response," said Dr. A. Ralph Rosenthal, head of division of ophthalmology at Stanford University School of Medicine.

Previously, a program of breast self-examination for cancer was aired nationwide, but no measurement of audience response was done.

Rosenthal, Dr. Milton Flocks, a clinical professor of ophthalmology and Jerry Hopkins developed the test over a year ago under a grant from the National Society for the Prevention of Blindness.

They conducted the test in Columbus in cooperation with QUBE and the department of ophthalmology at Ohio State College of Medicine.

The Cable TV station QUBE was chosen for the testing because it is the only station in the country with computer feedback, said Rosenthal.

Viewers simply pressed a button near their set to respond to questions such as whether they passed or failed the test, what their age and sex was, and what they felt about the test.

The test consists of two parts. In the first, viewers are instructed to stand about 12 feet away from the TV screen and read standard eye chart letters with one eye at a time.

In the second part, viewers are told to sit at a distance from the set equal to the diagonal measure of the TV screen, and stare at a spot in the center of the screen while other dots blink on and off. This tests peripheral vision. Again, each eye is tested separately.

The test runs about 12 minutes and the viewers compare their responses to the correct ones. If they fail the test, they are urged to see an ophthalmologist.

So far in testing at the Stanford Eye Clinic and in a small field trial of 200 individuals, the TV test has been shown to be about 90 percent accurate, said Rosenthal.

That is, 90 percent of the viewers with normal vision, as determined by an ophthalmic examination, passed the TV test; and 90 percent of those with defective vision failed.

"The findings of the Ohio test will be made available in a few months," said Rosenthal.

"If the accuracy of the test is still about 90 percent then broadcasting from conventional stations will soon begin—at first by local TV stations and then perhaps a nationwide test," said Flocks.

Until now, the principal visual screening of the general population has been carried out by the public schools, motor vehicle licensing bureaus, and the military service.

However, there are large numbers of people unaware of their visual defects who could be easily screened through their television sets, said Flocks.

"Other countries have asked for copies of the test," said Rosenthal, "and it may have particular relevance to people in developing countries who may have television, but no regularly provided eye examinations."

STANFORD—A year-long state investigation into alleged "double-billing" by Stanford University Medical Center has been closed after Stanford and State officials reached agreement on the method that should be used to pay faculty physicians for services provided to Medi-Cal patients.

Stanford agreed to lower by about $100,000 a year its cost claims to Medi-Cal for three years, 1975 through 1977, during which Medi-Cal paid Stanford about $9 million per year.

The exact amount of the readjustment will not be known for about three months, when routine audits for those years are concluded.

The State informed Stanford that no adjustments are necessary to the professional fees which Stanford faculty physicians have charged Medi-Cal for the direct medical and surgical services rendered to Medi-Cal patients.

Announcement of the agreement was made Thursday, Feb. 8 in a press release issued by the State Department of Health Services in Sacramento.

Robert C. James, deputy director of the Department's Audits and Investigations Division, said the agreement "resolves a complicated reimbursement problem in a constructive, equitable manner."

He announced "that settlement of these cost reimbursement principles brings to completion the...investigation of Stanford's Medi-Cal professional fee and cost-reimbursement system."

Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the School of Medicine, said Stanford is pleased with the agreement.

"Adjustments are not uncommon in claims of that size in an extremely complex two-part reimbursement system," said Crowley.

The agreement covers the principles and the method which Stanford should utilize in preparing its annual cost report to recover the cost of indirect patient services provided by its faculty physicians.

Under Medi-Cal, teaching institutions are authorized to recover the costs of their faculty providing indirect patient services. Such services include medical administration, medical direction and supervision of the services rendered by interns and residents.

-more-

In addition faculty physicians are authorized to bill Medi-Cal professional fees for the separate, direct medical and surgical care provided to patients.

The agreement covers these areas:

• For purposes of Medi-Cal reimbursement, faculty patient care efforts will be determined by use of an effort report prepared by the individual faculty members.

• Direct medical and surgical professional services to Medi-Cal patients will be reimbursed exclusively through payment of a professional fee.

• Indirect faculty effort to providing professional services to Medi-Cal patients will be paid for by Medi-Cal to the institution through the hospital cost reimbursement mechánism.

Stanford's cost reports for the years 1976 and 1977 will be adjusted to apply the methods agreed upon, said Crowley.

In addition, although the Medi-Cal cost report for fiscal 1975 was previously audited by the state and closed, Stanford agreed to reopen that cost report and adjust it according to the agreed upon principles.

The Medi-Cal investigation of Stanford was touched off by allegations of "double-billing" made last year by the Union of American Physicians.

Still to be resolved is another issue currently being investigated by the State Board of Medical Quality Assurance (BMQA). It concerns the legality of Stanford faculty's medical practice plan.

Crowley stressed that the matter being investigated by the BMQA is entirely separate from the Medi-Cal issue being concluded as a result of the agreement with the state.

A complaint filed with the BMQA by Dr. Eugene Dong, Jr., an associate professor of cardiovascular surgery, has alleged that the faculty practice plan violates a section of the California Business and Professions Code.

The code allegedly prohibits salaried faculty physicians employed by medical schools in the state from charging professional fees.

But at a recent hearing in Sacramento, California medical schools, including Stanford, have asked the legislature to clarify the law "because no medical school in the country provides, or could provide medical services free of charge."

STANFORD—Improving patient services, upgrading physical facilities, cost containment, and better communication all are part of Stanford University Hospital's "commitment to excellence" in patient care and management.

These goals are part of the introduction of the Stanford University Hospital budget for 1979-80. It was prepared by Dr. Peter Levin, associate vice president and executive director of Stanford University Hospital, and Gary Mecklenburg, hospital administrator.

Mecklenburg presented the goals statement Monday, February 5 at a meeting of hospital managers in the Medical School's Fairchild Auditorium.

The primary component of a commitment to excellence in patient care is a commitment to excellence in management, read the statement.

"It challenges our entire management team to establish specific goals and objectives for 1979-80, and identify the necessary resources to accomplish them.

"The past 18 months have been enormously demanding on the Hospital and Medical Center organization. In many instances organizational problems have been resolved through 'crisis management.'

"Together, we have successfully responded to accreditation and licensure, and continuous financial pressures. Throughout it all, Stanford University Hospital has provided outstanding patient care, which we will continue" in the future.

The statement listed the following goals and objectives:

- expanding and upgrading physical facilities according to an "action plan," to create a better environment for both giving and receiving care.
- implementing an effective cost-containment program.
- improving communications, and the access of hospital services to the public and physicians.
- improving employee and managerial excellence, so that a "humanistic" attitude is achieved at all levels of the hospital organization.

To resolve space and functional problems in the hospital, the San Francisco consulting firm of Stone, Marraccini and Patterson recently was hired to develop an action plan.

The plan, which is scheduled for completion in July, 1979, may include renovation of patient care units, construction of new areas and solutions to functional deficiencies and code citations identified in last year's accreditation survey.

-more-

Construction has already begun on the renovation of the intensive care and normal newborn (West) nurseries.

To improve communication, the hospital has initiated a survey of medical staff, patients and the community.

The financial planning process is being reviewed in response to "demands for efficiency and effectiveness in financial and hospital management," according to the statement.

Other projects include a computer-based information system, materials management program, and an improved patient admitting system.

At the same time, cost containment continues to be a major concern at the hospital.

"Despite our efforts at cost containment, the average cost per patient per day at Stanford has increased substantially during the past five years," read the statement.

"It appears that this increase is leveling, but there is still concern that the hospital will be faced with additional controls which may limit its financial resources."

Some of these controls include mandatory cost containment, which will be proposed by the Department of Health Education and Welfare if voluntary containment is not successful, and possible cuts of $400 million in reimbursements for care given to Medicare and Medical patients.

"Although cost containment legislation seems imminent," read the statement, "we cannot allow ourselves to be overwhelmed by the influence of external control.

"The emphasis should be to control the rate of increase through our own sound management performance."

To that end, the hospital is developing a comprehensive cost containment program.

While meeting the health needs of the community is the hospital's first priority, "we cannot lose sight of the fact that we are part of a leading medical center and great university with which we share the additional goals of teaching and research," read the statement.

"We can most effectively support these goals by assuring outstanding patient care programs in a well-run hospital."

TWO STORIES: Bob Beyers
FOR IMMEDIATE RELEASE
STANFORD—

Stanford trustees have approved a 13.5% increase in Medical School tuition, effective this fall.

The new rate will be $2,038, compared to $1,796 currently per academic quarters.

A similar rate of increase can be expected during 1980-81 and 1981-82.

This will conform with the Board of Trustees decision in December to phase in a return to the historical relationship between tuition and the cost of medical education over a three-year period. This cost is now estimated at more than $35,000 per student annually.

Taken in conjunction with other tuition increases within the University, the 1979-80 rate for future M.D.s falls within President Carter's wage price guidelines.

The increase is half that initially proposed for entering students by the University administration in December, when a 27.6% boost was recommended. It is slightly below the 14.6% increase suggested at that time for continuing students.

At their December meeting the trustees voted that "tuition for 1979-80 in the Medical School be set so as to meet the tuition objectives proposed over a three-year period." This meant restoring the ratio between tuition and costs which prevailed in 1972.

The board authorized Trustee President Peter Bing, Academic Affairs Committee Chairwoman Barbara Finberg, and Finance and Development Committee Cochairmen Roger Lewis and William Timken to approve a modified increase.

Financial aid funds will be increased to assure that attendance at Stanford Medical School is not prevented by inadequate assistance.

—30—

FOR IMMEDIATE RELEASE
STANFORD—

Dr. Thomas C. Merigan, professor of medicine, will head the search for a successor to Dr. Clayton Rich at the Stanford Medical Center, University President Richard W. Lyman has announced.

Dr. Rich resigned his administrative posts as vice-president for medical affairs and dean of the Medical School Jan. 1.

Besides Merigan, who heads the division of infectious diseases, those serving on the search committee will include Dr. John A. Collins, chairman of surgery; Dr. Kenneth L. Melmon, chairman of medicine; Dr. Hugh O. McDevitt, professor of immunology; Dr. Irving L. Weissman, associate professor of pathology and chairman of the Medical School Faculty Senate; Dr. Joseph Kriss, professor of radiology and head of the division of nuclear medicine.

Also: Dr. Ruth T. Gross, professor of pediatrics and head of ambulatory pediatrics; Dr. Stanley N. Cohen, chairman of genetics; Dr. Robert I. Lehman, chairman of biochemistry; Arthur Walker, associate professor of applied physics and associate dean of graduate studies; William F. Miller, professor of computer science and of management; Dr. Walter Bortz, clinical assistant professor of medicine and physician at the Palo Alto Medical Clinic; and Joshua Prager and Tony McCain, medical students.

Editors: Photo of Ingelfinger available if not included.

STANFORD—"The Medical Press, Professional and Lay" will be the subject of three public lectures Feb. 12, 14 and 15 at Stanford University School of Medicine.

The talks by Dr. Franz J. Ingelfinger, editor emeritus of the *New England Journal of Medicine,* will be given under auspices of the 23rd Herzstein Lecture Series. Each lecture is free and will begin at 5:30 p.m. in Sherman Fairchild Auditorium.

Ingelfinger's lectures will be: "Medical Journals Today" Feb. 12, "The Race for News" Feb. 14, and "Medical Communication in the Future" Feb 15.

Ingelfinger is visiting lecturer on medicine at Harvard Medical School and Professor of medicine, emeritus, at Boston University Medical School.

He had a long and distinguished career after graduating from Yale (A.B. 1932) and Harvard (M.D. 1936), including the editorship of several medical journals and the editorial board membership on several others. He was a member of the editorial board of the *New England Journal of Medicine* during 1961-67 and editor in 1966-67.

He holds many awards, lectureships and honorary degrees, including the Distinguished Teacher Award for Leadership in Medical Education from the American College of Physicians (1975), the Abraham Flexner Award for Distinguished Service to Medical Education, Association of American Medical Colleges (1976), the Thannhauser Medal (1978) and is a Kober Medal designate of the Association of American Physicians (1979).

The Morris Herzstein Lectures were established in 1929 to honor the late San Francisco physician. The lectures, which are alternated between the University of California Medical School in San Francisco and Stanford Medical School, are designed to attract scientists "of outstanding achievement."

A humanitarian, Herzstein (1854-1927) founded the first fully-equipped clinical laboratories in San Francisco upon return from his native Germany in 1891.

STANFORD—Heating by ultrasound caused shrinkage in nearly 70 percent of superficial head and neck tumors, and in 50 percent of a variety of surface tumors in patients treated at Stanford University Medical Center.

Ultrasound heating may be particularly useful in treating squamous cell carcinomas (solid tumors) of the head and neck, either by itself, or combined with surgery and radiation, according to researchers Jane B. Marmor, M.D., Douglas Pounds, Ted B. Postic, and George M. Hahn, Ph.D.

However, they cautioned, most of the responses were partial, and the patients were followed for an average of only five weeks.

Their findings were reported in the January 1979 issue of the journal *Cancer*.

In the study, 30 patients were given ultrasound treatments three times a week for two weeks.

Ultrasound energy (of a frequency of one to three megahertz) was directed through a four centimeter transducer held over the central part of the tumor. Thermocouple needles placed in the tumors recorded the increase in tissue temperature as they were heated.

In an initial patient group, tumors were heated to 43 degrees Centigrade (108 degrees fahrenheit) for 30 minutes during each treatment. Later groups were treated at 44 and 45 degrees.

Changes in the size of the tumors were recorded after each teatment.

Better responses were obtained in patients who had received no prior treatment or radiation alone than in those who had received chemotherapy.

The treatments were given with minimal side-effects. Five treatments resulted in small superficial burns, and some of the patients reported significant pain during treatment.

More precise delivery of the ultrasound with improved equipment should help overcome this problem, stated the researchers.

The use of ultrasound as a treatment for cancer was investigated in the 1930s and shortly after World War II, but the role of heating was not completely understood, and there was little interest in it until the 1970s.

In 1976, Marmor and Hahn reported that ultrasound caused shrinkage in 50 percent of surface tumors in dogs, cats and mice.

The Stanford group is now developing multiple transducer systems which will enable them to treat larger and some deep-seated tumors. Their research is supported primarily by the National Cancer Institute.

STANFORD—Construction crews will begin interior completion of the third floor of Stanford Medical School's Sherman Fairchild Building later this month.

The building, which already houses the school's Departments of Structural Biology and Neurobiology, was actually completed in 1976. However, the structure's top floor has remained a shell until funding became available.

Stanford University Trustees have authorized $2.1 million for completion of the floor, which has 20,800 gross square feet of space. The floor will accommodate laboratories, offices and support facilities for the Department of Medical Microbiology. Included among the labs will be P-3 biosafety facility to be used in recombinant DNA research.

The project was designed by architect planners Stone, Marraccini and Patterson of San Francisco under supervision of university project manager Elvia Garwood. The contractor is Carl W. Olsen of Menlo Park.

Most of the project cost ($1.5 million) is being funded by a grant from the Max C. Fleischmann Foundation of Reno, Nev. Additional funding is coming from the Horton Gift Fund and an "anonymous" donor.

During construction about 35 parking stalls will be lost to accommodate a work staging area.

The Fairchild Building, which is built around an atrium, is part of a two-structure complex which also includes a 386-seat auditorium. The building already houses laboratories, conference rooms and administrative offices.

The $10 million building and auditorium are the result of an $8.25 million gift from the Sherman Fairchild Foundation of Greenwich, Conn., and is named for the founder of the Fairchild Camera and Instrument Corp. and Fairchild Industries.

Additional funds came from Mrs. George A. Winzer of La Jolla, Calif., a longtime benefactor of the medical school.

STANFORD—The February meeting of the Stanford Faculty Women's Club will feature an address on sleep and sleep disorders by Dr. William Dement, director of Stanford's Sleep Disorders Center.

The meeting, which is open to the public at no charge, will be held in Fairchild Auditorium at Stanford Medical School on Thursday, Feb. 8, starting at 8 p.m.

Dement's talk, "Sleep: A Cure, a Blessing or Both?" will be an explanation of how sleep does its job best. He will also discuss how sleep can kill, and explain why snoring is considered a disease. The amount of optimal sleep and insomnia will also be highlighted.

Dement is professor of psychiatry and behavioral sciences at Stanford Medical School.

STANFORD--A San Francisco consulting firm has been hired to develop an "action plan" for renovation and construction at Stanford University Hospital over the next five years, according to Mary Catherine Krawec, associate administrator for operational planning.

Stone, Marraccini, and Patterson was chosen because of its experience in health planning, and prior work at Stanford, including design of the Sherman Fairchild building in 1974, said Krawec.

The firm will develop a comprehensive plan during the next six months to resolve problems of functional deficiencies, code citations, and major building systems.

Stanford hospital received a full two-year accreditation by the Joint Commission on Accreditation of Hospitals (JCAH) in July 1978.

That accreditation, based on a survey in April by the JCAH, the California Department of Health, and the California Medical Association, requires that a plan be developed and implemented to correct deficiencies noted in the survey.

The next accreditation survey is scheduled for spring, 1980.

In the action plan, construction projects will be "packaged" in a logical sequence, taking into account code citations, hospital priorities, costs, and in ways which reduce disruption of hospital operations, said Krawec.

Once completed, the plan will be reviewed by the University Board of Trustees, and by the appropriate governmental agencies.

"Our goal is to improve the functioning of the hospital in terms of patient care and working environment, solving physical problems," said Krawec.

"Having an action plan will keep us from creating new problems as we attempt to solve others."

High priority projects include planning for completion of the Phase 1 building and construction of new operating rooms.

However, "There is very little of the hospital which is not going to come under review," she said.

The action plan will be prepared as a joint effort by the consultants, hospital administration and staff, and a committee of physicians representing equally community and faculty doctors.

In addition, hospital and medical staff members and community physicians are urged to contact Krawec with any suggestions to the plan. She can be reached at 497-5377.

STANFORD--Researchers at Stanford University School of Medicine have developed a technique which may one day improve corneal transplantation.

The cornea is a transparent, dome-shaped membrane made up of five layers which covers the iris and pupil of the eye.

The innermost layer, the endothelium, pumps fluid out of the cornea, keeping it thin and clear. In some eye diseases, this layer breaks down, and fluid accumulates in the cornea, blurring vision.

Presently, these conditions are treated by transplanting all five corneal layers from the eye of a donor into that of the patient.

The new technique would remove only the damaged endothelial layer from the patient's cornea, "seed" the cornea with new cells grown in culture, and replace the cornea with its new endothelium back in the eye.

This would avoid the need for donated corneas in treating endothelial diseases. It may also reduce rejection of the foreign tissue by the body, since only a single layer is replaced rather than the entire cornea.

The researchers, Drs. David M. Maurice and James P. McCulley, and Marcia M. Jumblatt, so far have limited their studies to rabbits, and admit that testing in humans is several years away.

But their work, reported in the December 1978 issue of Investigative Ophthalmology and Visual Sciences, is the first demonstration that endothelium grown in tissue culture can regain normal function when replanted in the eye.

In the report, endothelial cells were grown in culture, and then placed on rabbit corneas from which the native endothelium had been removed. The new cells were allowed to grow over the surface of the corneas for one to three days, and the corneas were then transplanted into rabbit eyes.

The grafted corneas were examined daily by a microscope technique, and their thickness measured.

Only four of 19 attempted grafts were successful, that is, they did not swell with fluid or become cloudy. Fluid build-up indicated that the endothelium was not working.

The failed grafts may represent problems with the culture used to grow the cells, stated the researchers.

Currently, the Stanford group is trying to speed up the process of "seeding" the corneas, so that it can be done in minutes instead of hours.

One possibility involves lining the inside of the cornea with a porous membrane covered with a layer of endothelium which has been grown in culture. This would allow physicians to "stick" a new layer onto the cornea quickly.

"Our ultimate aim is to have eye banks grow and maintain endothelium which could provide on demand the tissue for transplantation," they said. ###

STANFORD--Preliminary drawings for the renovation of Stanford Hospital's Neonatal Intensive Care Unit (ICU) have been approved by the State Offices of Development and Licensing.

Construction is due to begin in July, 1979, according to Mary Catherine Krawec, associate administrator for operational planning.

San Francisco architects Kaplan, McLaughlin and Diaz are now working on the final drawings, which will then be reviewed by the state prior to beginning construction, she said.

Temporary renovation of the unit, including knocking down two walls and providing additional storage areas, was completed in December.

The unit had been chronically short on space, and the nursing staff threatened to resign en masse in October unless renovations were made.

To accomodate the Neonatal ICU during construction, the normal newborn (West) nursery will be remodeled beginning February, said Krawec.

Several patient rooms near the nursery will be converted for the care of normal newborns, according to a plan by Palo Alto architects Almeter and Finley.

Once the construction is completed, the normal newborns will be moved back into the upgraded nursery, and the remodeled patient rooms will be made available for use by high-risk mothers.

The University Board of Trustees approved $1 million for the renovation of the neonatal ICU over a year ago although the final figure has not yet been determined.

Dean / VP for Med Affairs

STANFORD UNIVERSITY MEDICAL CENTER

News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 497-6911

STANFORD—Stanford University President Richard W. Lyman announced Thursday, Feb. 15 that he will separate the position of Vice President for Medical Affairs and Dean of the School of Medicine.

Lyman made the announcement in a letter to the committee searching for a successor to Dr. Clayton Rich who resigned in January. Rich held both administrative positions.

"I am asking you to search for a Vice President for Medical affairs at a time when it is increasingly clear that the incumbent will have different responsibilities from the last two holders," Lyman wrote.

"Specifically, we are moving toward a greater degree of de facto separation between the Hospital and the Medical School," he continued. "To put it somewhat differently, there are compelling reasons to believe that both entities will fare better if each has strong, independent leadership."

Lyman said such a leadership will consist of a Dean for the Medical School to whom (academic) departments will report, and a director for the Hospital whose authority will be independent of the Dean's.

"Both of these persons will report to the Vice President for Medical affairs, who will need to have substantial management abilities as well as keen sensitivity to issues of biomedical policy, federal, state and local, and the capacity to define and articulate the institution's positon on them," Lyman said.

"Inevitably, he added, "the precise duties of the position will be defined in part by the qualities of the individual who takes it."

Lyman noted that "this is an important time in the history of the Stanford Medical Center.

"Every university medical center in the country is actually or potentially at risk because of the uncertainties afflicting national policies with respect to medical education, research, and health care."

Lyman's letter constitutes the formal charge to the search committee whose membership was announced last week.

The committee is headed by Dr. Thomas C. Merigan, professor of medicine and head of the division of infectious disease in the Medical School.

FOR IMMEDIATE RELEASE
STANFORD—

Is Stanford University School of Medicine becoming antiintellectual and antiscience?

Forty-one senior faculty members think so. They have signed a letter asking others to join them to help "bring about the necessary changes in Medical School policies and procedures."

The faculty members are concerned because of the falling scores of medical students on the national boards. Thirty-seven percent of the students tested for their knowledge of basic medical science in 1978 failed all or part of the test.

The Faculty Senate of the School is considering recommendations of the Committee on Student Evaluation for developing and enforcing more rigorous student performance standards.

The letter was authored by Dr. Avram Goldstein, an eminent pharmacology professor. It was signed by both clinical and basic science faculty, including a Nobel laureate, seven department chairmen, and the chairman of the faculty senate.

Goldstein wrote: "If we had set out deliberately to lower our academic standards and the performance of our students, here are some of the things we might have done:

* "Institute a totally elective curriculum, without structure and without required sequence, essentially a chaotic array of course offerings, with no obligation for the student to demonstrate competency in any of the basic areas of medical science.
* "Abolish letter grades and all special recognition of superior performance such as honors, the Alpha Omega Alpha honor society, Dean's list etc.
* "Permit students to drop courses at any time before a final examination, or allow students to decide not to take a final examination whenever it suits their convenience not to do so.
* "Refuse to record failures on the student's record, and set up a committee on academic performance that refuses to terminate any student, regardless of how incompetent or inept he or she may be.
* "Abandon the faculty's responsibility to direct the academic programs of the School, and give undue weight to the opinions of students, forgetting how brief is their passage through the School, and how poorly equipped they are with the perspective, experience, and wisdom needed to know what is really best for their own medical education.
* "Respond passively or not at all to attacks upon scientific investigation and intellectual pursuits in general as 'elitist.'
* "Eliminate some of the most intelligent and promising applicants for admission because they have too strong an interest in science.
* "Denigrate scientific medicine, and dignify antiscience, by offering a platform to the practitioners of fads, superstitions, and magic."

Goldstein said many refuse to acknowledge that "the unique primary mission of this medical school—what our faculty is best equipped to do—is to train the next generation of clinical investigators, basic medical scientists, and academicians."

"As we have sown, so have we reaped," he concludes.

One of the letter signers, Dr. Arthur Kornberg, professor of biochemistry, echoed similar concerns in an article published in the Stanford medical alumni magazine last fall.

"It is imperative," he wrote, "that medical scientists and their institutions, faced with diminishing resources, work even more devotedly and single-handedly to strengthen the scientific fiber and foundations of medicine. "We must have affirmative action for scholarship. Otherwise medicine will revert to empiricism, which means it will be approaching witchcraft once again."

STANFORD—

Dr. Marcus A. Krupp, director of the Palo Alto Medical Research Foundation, has been appointed director of the Department of Medicine's community teaching service in the east wing of Stanford University Hospital.

His three-year appointment, effective April 15, was announced by department chairman Dr. Kenneth L. Melmon Thursday, March 29.

Krupp, a member of the Medical School's clinical faculty, replaces Dr. Lawrence V. Basso, clinical faculty member and endocrinologist at the Palo Alto Medical Clinic.

Basso resigned recently after directing the service since 1976.

"Dr. Krupp is considered by the house staff and medical students to be one of the best attending physicians in the service," said Melmon.

"He has had continuous interest in the Department. For example, he helped establish a position on the Stanford faculty for Dr. Jack Remington."

Remington, a well-known researcher in infectious diseases, is a member of the Research Foundation staff.

"In addition," said Melmon, "Dr. Krupp has received strong support from community physicians who use the service. It is hard to think of another person better suited for the job."

The service, located on the first floor of the hospital's east wing, is one of two community teaching services in the Department of Medicine which provide bedside training of medical students and house staff by community physicians who admit their patients to the hospital.

The other service is located on the second floor of Hoover Pavilion. It is called the Bloomfield Service, in honor of the late Dr. Arthur L. Bloomfield, who chaired the department in the 1950s.

Dr. Lenore Sheridan, clinical faculty member and head of pulmonary medicine at the Palo Alto Medical Clinic, is director.

At any one time, 10 residents, interns and medical students receive instruction from the community physicians who admit patients to the services.

The east wing service was established in 1969 to enlarge the clinical experiences of house officers and students, and to increase the working relationship between community physicians and faculty.

Krupp, who has taught on the service for several years, said it is an example of "good University-community relations."

"Many community physicians are happy to have their patients on a teaching service, where they benefit from some of the best young minds on our house staff, and from 24-hour coverage," he said in an interview.

As director, "I want to see to it that the high standards of patient care and teaching provided by the service under Dr. Basso are maintained."

STANFORD—

Comprehensive regional programs in perinatal education for both mothers and health professionals are being developed by doctors and nurses at Stanford University Hospital and Santa Clara Valley Medical Center in San Jose.

The programs, which will be directed by faculty of the Stanford University School of Medicine, are designed to improve the outcome of high risk pregnancies throughout the central coast region of California.

Women at high risk for complications during pregnancy include those with diabetes, hypertension, histories of medical problems, and social or emotional problems.

Certain age and racial groups also are at higher risk for complications, particularly if they do not receive adequate prenatal care.

For instance, the California Department of Health Services has reported recently that babies born to women under 15 are two to four times more likely to have neurological abnormalities than those born to women aged 20-25.

Yet, 45 percent of these mothers fail to receive prenatal care in the first trimester of pregnancy.

In addition, the infant death rate may vary by a factor of six between two different socioeconomic groups in neighboring communities, the report stated, depending on the availability of health care.

Regional perinatal care is already available at Stanford and Valley Medical Centers. Services include emergency transport of high-risk mothers and seriously ill infants to intensive care facilities, and coordination of intensive care nurseries throughout Northern California by an infant medical dispatch center based at Stanford.

One of the new programs will provide perinatal outreach services to hospitals in 13 communities from San Mateo County to Santa Maria in Southern California.

The aim of the program is to reduce rates of death and illness associated with high-risk pregnancies, improve the early acute care of critically ill infants, and enhance the ability of nurseries in community hospitals to care for sick infants during recovery, says program coordinator Dr. Alvin Hackel, associate professor of clinical anesthesia and pediatrics at Stanford.

To accomplish these goals, Stanford physicians and nurses will conduct seminars in the participating communities four times each year, and will continue a lecture series at Stanford on perinatal care and infant resuscitation,

Nursing teams from Stanford's obstetrics and pediatrics units will provide consultation and bedside teaching in the care of sick infants for the nursing staffs of participating hospitals.

Community physicians may also obtain consultation from medical staff at Stanford.

Closely associated with the outreach program is an educational program for high risk mothers directed by Dr. Kent Ueland, professor of gynecology and obstetrics at Stanford.

This program will provide educational materials on nutrition, risk factors, and basic guidelines to good prenatal care for patients at stanford and in outlying communities

It is the first organized prenatal education program at Stanford, says Ueland.

The outreach and education programs are being supported this year by Stanford, and by grants from the Mead Johnson Foundation and the National Foundation of the March of Dimes.

Santa Clara Valley Medical Center also is developing a health education program for high risk mothers, geared to fit their individual needs.

High risk mothers will be interviewed, and will receive an "educational prescription," which may include nutritional counseling as well as instruction in prenatal care, says program director Dr. Paul Hensleigh, associate professor of gynecology and obstetrics at Stanford.

The Valley Medical Center program is supported this year by a $219,000 grant from the State of California.

STANFORD—

Young women who suffer from menstrual cramps are invited to participate in a Stanford University Medical Center study of a drug which may control the pain.

Menstrual cramps, known as dysmenorrhea, occur in nearly 50 percent of all adolescent women, and are responsible for the majority of short-term school absenteeism in females, according to Dr. Jerry Klein, postdoctoral fellow in pediatrics, who is conducting the study with Dr. Iris Litt, associate professor and director of adolescent medicine at Stanford.

According to Klein, body substances called prostaglandins recently have been found to cause dysmenorrhea, whose symptoms are not only cramps, but may include nausea, vomiting, fatigue, headache and muscle stiffness.

Over a four-month period, Klein will be studying a prostaglandin inhibitor effective in adults, to see if adolescents will also obtain relief.

Due to the design of the study, Klein prefers that the drug's identity not be disclosed ahead of time to study participants, but it is a commonly used over-the-counter drug.

Volunteers should be under 21 years of age. For more information call Dr. Klein or Lynda Spencer at 497-6891.

STANFORD—

The role of the nurse is changing.

From cancer chemotherapy to hemodialysis, nurses are performing functions today once exclusively reserved for doctors. This is the conclusion of a special report on nursing at Stanford published in *The Healing Arts*, a magazine of the Stanford University Medical Center.

For example, in the early 1960's when dialysis was still experimental, doctors performed the treatments, and "all the nurse did was bring coffee and doughnuts," recalls Pam Simmons, clinical nursing coordinator of the Stanford Hemodialysis Center. Today, most of hemodialysis at Stanford is done by nurses.

The nurse's role also has expanded in the areas of intensive and emergency care, the magazine found.

At Stanford, one and sometimes two nurses stay continuously at the bedside of patients who have had open heart surgery, checking vital signs, adjusting the instruments which breathe for them or help pump their blood, and alerting physicians to changes in condition.

"This is highly technical care," says Laurie Gunderson, clinical nursing coordinator of the North Intensive Care Unit (ICU). "Nurses used to be recorders of patient data, and were not expected to help in diagnosis and patient evaluation.

"Today, they must know what the numbers mean and how to change them."

In the emergency department, nurses may be helping doctors bind a wound one moment, and calming a psychiatric patient the next.

"They form the cornerstone of patient care in cases of rape or child abuse," says emergency department director Dr. Michael Eliastam.

"They may be responsible for staying with the patient during the physical examination, talking with the family, arranging follow-up with appropriate health professionals, and even providing some counseling themselves.

"They are there from beginning to end."

A relatively new specialty for nurses is oncology, cancer chemotherapy. Five nurses at Stanford are certified to give cancer-fighting drugs intravenously, and to teach patients how to take their other medications at home.

But the technical expertise required of these nurses is only part of their job.

"We will spend anywhere from 20 minutes to two hours with patients while giving their drugs, and during this time we can often discover what problems they and their families may be facing," says Linda Dodds, head nurse of the Oncology Day-Care Center at Stanford.

"Cancer is a frightening disease that carries with it many myths and misunderstandings," says Dodds. "We provide important support to patients, often by simply talking to them on the telephone."

-more-

2-2-2 Patient education has become another important part of the nursing role, particularly as more people are being treated as outpatients, and as those who are hospitalized are sent home earlier.

"In the hospital, the environment is regulated—diet, exposure to sunlight, exercise—but at home, patients must do this regulation themselves," says Vera Waechter, R.N., manager of clinical patient services in Stanford University Clinics.

"To do this, they must understand their disease. Their families must also understand, so they can be supportive," she says.

In the Oncology Day-Care Center, nurses help patients minimize the nausea and other side-effects which often accompany chemotherapy by showing them how to take their medications properly.

Nurse Ann Schreier has developed an audiovisual program to tell patients with Hodgkin's disease and their families about the disease and what to expect during treatment.

Other education programs are in use in the coronary care unit and the dermatology clinic.

"We are involved in patient education every day," says hemodialysis nurse Pam Simmons. "We've grown up a lot from being very demanding of patients, to recognizing that they have the right to make their own decisions.

"If they are to make those decisions, we must give them information."

There has been real progress in the nursing profession in the last 10 years, says Jeanne DeJoseph, R.N., Ph.D., assistant nursing service director at Stanford. "But we have not yet come to where we need to be."

Paralleling the increased roles for nurses as technical experts, educators and counselors, has been a 300 percent increase in salaries for nurses in California during the past decade. The 1977 annual wage, according to the California Hospital Association, was about $10-15,000.

Yet California is plagued by a chronic shortage of nurses. A 1978 report by the CHA indicates that nearly half of all registered nurses quit their jobs each year, and that 9,000 nursing positions in hospitals and nursing homes are vacant.

Relocation is cited by the CHA report as a major reason for the large turnover. Nurses may relocate because of family moves, but "reality shock" is another factor.

Crowded working conditions, long hours, and the monotony of some aspects of day-to-day patient care have all had their toll on the profession.

Stanford is not immune from the problems of staff shortage and high turnover rates, but it has a high caliber of nurse, and in some units, turnover is close to zero.

Nursing service director Duane Walker cites opportunities for learning, plus the "glamorous"aspect of working with physicians on several frontiers of medicine for attracting nurses to Stanford.

In addition, the nursing service is developing programs to improve incentive and job satisfaction.

Peer groups and psychiatric liaison services are available to help nurses cope with stress.

The promotion system rewards nurses with greater and more varied responsibility as they gain knowledge and experience.

And nurses can do research in areas such as the physiological and psychosocial responses of patients to nursing care, and the role of nursing in care of the premature infant.

"Research is not the answer to all of our problems," says Walker, "but it will contribute to the quality of patient care here, and to the practice of nursing nationally."

Emergency department nurse Barbara Behrens demonstrates the use of the defibrillator during inservice training at Stanford.

Oncology nurses participate in physician conferences, and contribute to patient care as part of the medical "team."

Nurses work with doctors, respiratory therapists and paramedics to transport seriously ill infants and adults to Stanford's intensive care units from all over Northern California.

Nurse Lynn Hewett conducts an exercise treadmill test of a patient with suspected coronary artery disease. Until last year this test was performed exclusively by doctors.

STANFORD—

Sir Bernard Katz, a Nobel laureate in physiology and medicine, will deliver the Lane Lectures on April 2,4 and 5 at Stanford University School of Medicine.

Each lecture is open to the public and begins at 5 p.m. in the school's Sherman Fairchild Auditorium.

Katz, emeritus professor of biophysics at University College, London, is widely recognized for nerve and muscle studies, particularly on the physicochemical mechanisms of neuromuscular transmission.

His first lecture on Monday, April 2, is entitled "Elementary Units and Synaptic Functions." It will be followed on Wednesday, April 4, by "The Vesicular Hypothesis of Transmitter Release" and "The Properties of Post-Synaptic Ion Channels" on Thursday, April 5.

Katz shared the Nobel prize for medicine in 1970 with Ulf von Euler of Sweden and Julius Axelrod of the U.S.

In 1939 Katz joined J.C. Eccles Laboratory in Sydney, Australia, where he collaborated with Eccles and S.W.Kuffler in neuromuscular research. He was appointed to University College, London, in 1946 as assistant director of research and the Henry Head Research Fellow (who is appointed by the Royal Society). He became professor of biophysics there in 1952.

Katz, who received his M.D. from the University of Leipzig and a Ph.D from London University, was knighted in 1969. In 1967 he was awarded the Baly Medal from the Royal College of Physicians and the Copley Medal from the Royal Society.

The Lane Lectures, which were first given in 1896, were established by Dr. Levi Cooper Lane, one of the founders of Stanford Medical School. The school was originally known as Cooper Medical College until it moved from San Francisco to the Stanford campus in 1959.

STANFORD—

Stanford University School of Medicine should establish and enforce more rigorous student performance standards, a committee of the School's faculty senate recommended Friday, March 23.

The committee endorsed the elective curriculum and pass-fail system, but it urged the senate to develop procedures for dealing with the marginal performers.

"The faculty of every course must identify those students whose performances are marginal by a uniform standard," the committee said.

And each department should establish an "appropriate" performance standard for judging student work.

Headed by Dr. Ruth T. Gross, professor of pediatrics, the committee said it expects its proposals to address the dissatisfactions of both faculty and students with the present evaluations.

In a related move, the School's executive committee, acting in response to the falling National Board scores of Stanford medical students, adopted a strong recommendation to the faculty senate calling for tougher standards.

The recommendation would require each basic science department to obtain from all students a demonstration of competence in basic sciences prior to graduation.

A majority of the faculty polled by the Gross committee indicated that the present system provides inadequate information to evaluate student performance and fails to satisfy student needs.

"One fourth of the faculty think students now enter their clinical clerkships with basic science preparation below standard," the committee said. In addition, some believe Stanford is graduating a significant number of students whose knowledge is below acceptable standards.

Under the proposal, students who fail to meet the standard set by each department and the Committee on Courses and Curriculum would get a letter of marginal performance.

The students would then be required to meet with the faculty to discuss measures for achieving an unqualified "pass," the committee said.

Students receiving more than one letter of marginal performance in preclinical or clinical subjects will be counseled by the Student Affairs Office, and the Committee on Student Performance.

The committee may exercise several options.

-more-

According to the recommendations, no student would be allowed to drop a course in the clinical or preclinical years without the consent of the instructor.

The penalty for droping a course without consent will result in failure of the course, said the committee.

Prior to the end of the first clinical year, students would be required to pass Part I of the examination administered by the National Board of Medical Examiners. Passing Part II of the test would be required prior to graduation.

Part I tests students for their knowledge in the basic sciences, and Part II in clinical sciences. They are requirements for the medical degree at Stanford under the current system.

The committee recommendations describe in detail the mechanisms for improving feedback about examinations from faculty to students, designation of responsibility for clerkships and preclinical courses, and appeal mechanisms to resolve grievances and maintain the rights of students to due process.

The committee unanimously rejected the reinstitution of honor grades, academic awards, including the Alpha Omega Alpha Honor Society.

"Honor grades, particularly in the clinical clerkships, cannot be based on statistically sound methods of evaluations and they are not advisable," the committee said.

"Methods for recognizing excellence exist in the present and in the proposed system, and our students express satisfaction with the current approach."

Committee members included Duncan Govan, professor of surgery, ex-officio; Dale Kaiser, professor of biochemistry; Bernd Kutzcher, third-year student; Paul C. Letourneau, assistant professor of structural biology; Bob Loitz, fourth-year student; Saul Rosenberg, professor of medicine and radiology; and Kenneth Vosti, professsor of medicine, ex-officio.

The recommendations will be discussed by the faculty senate April 6 at 3:30 in Room S-102 of the Medical School.

STANFORD—

Stanford University researchers have taken a first step towards development of a simple blood test to screen pregnant women for fetal genetic abnormalities as early as 15 weeks into pregnancy.

"At present, it's a basic research finding which could turn out to have enormous practical significance," said Dr. Leonard A. Herzenberg, professor of genetics at Stanford University School of Medicine.

Herzenberg and his colleagues, Diana Bianchi, medical student, Jim Schroeder and G. Michael Iverson, research associates in genetics, and Howard Cann, professor of pediatrics and genetics, reported their findings in the March issue of the *Proceedings of the National Academy of Sciences.*

"We have shown that as early as 15 weeks into pregnancy, small numbers of fetal cells are present in the mother's bloodstream," Herzenberg said, an idea suggested previously but not proved conclusively until now.

The group used an instrument developed several years ago in Herzenberg's laboratory—the fluorescence-activated cell sorter (FACS)—to separate fetal cells from the mother's cells on the basis of their cell surfaces.

By examining chromosomes (the hereditary material) in cells obtained from the fetus, the geneticists said they can recognize certain abnormalities of the fetus at an early stage of pregnancy.

Currently, this is accomplished in the process of amniocentesis, where a needle is inserted through the woman's abdomen into the uterus to remove a small sample of cells from the amniotic fluid which surrounds the fetus.

But, "amniocentesis is an expensive, potentially risky procedure which is not applied to the population at large, and is reserved for pregnancies with a high risk of finding genetic abnormality," Herzenberg said.

-more-

In addition, amniocentesis must be performed by an experienced obstetrician, a fact which limits its availability to many women, Cann said.

Although pregnant women over 35 have a higher risk of giving birth to infants with chromosomal defects, a simple procedure for routine prenatal screening of pregnant women under 35 is also needed.

"Widespread screening is desirable because the relatively large number of pregnancies in women below 35 years means that they bear the majority of children with chromosomal abnormalities despite the relatively low risk of such abnormalities in pregnancies in this age group," the researchers said.

Among the remaining problems to be solved before the technique can become available is inducing the isolated fetal cells to divide.

Normally, chromosomes are spread out in the cell and are not visible under the microscope. Only when the cells divide, do the chromosomes condense enough to become visible.

"No one has yet succeeded in getting the fetal cells to divide in blood," Herzenberg explained.

Aside from Down's syndrome (mongolism), other conditions which can be detected by examining fetal cells are those defects due to chromosomal abnormalities such as extra chromosomes, missing chromosomes or chromosomal rearrangements, Cann said.

Since all the pregnant women in the study had fetal cells in their bloodstreams by 27 weeks into pregnancy, and many as early as 15 weeks, the researchers expect that it is a normal process rather than accidental leakage of cells into the mother's circulation.

However, Herzenberg added, "if there is a reason for this cell passage, we don't yet know what it is."

The National Institutes of Health and the National Foundation (March of Dimes) support the research.

STANFORD—

Thousands of students each year who make the decision to attend medical school are not admitted because they simply don't have all the vital information they need.

At least this is the opinion of Donald J. Solomon, who went through the whole process himself before being accepted. Now a third year student at Stanford University School of Medicine, Solomon has collected first-hand experiences into a book which serves as a comprehensive guide to all the "do's" and "don'ts" of applying for admission to medical school.

The book, *Getting Into Medical School* (167 pp., W.B. Saunders Co, Philadelphia, $5.75 paperback), represents a long-term project for Solomon, who began keeping notes and records on the process while still in college.

The book provides the reader with a step-by-step examination of the very important decision of whether or not to become a doctor, what courses should be taken in high school and college, and what marks are most important.

Furthermore, it discusses the New Medical College Admissions Test (MCAT), when, where and how to apply to medical school, how to prepare the necessary essay, the interview (including typical questions and corresponding answers), and expenses.

Solomon, who intends to enter academic medicine and research cites personal examples of friends and acquaintances throughout the book and the mistakes they made that ruined their chances for medical school.

One case history Solomon cites is Brian, who presented medical schools with a beaming 3.9 grade point average. Yet, he wasn't admitted anywhere. The reason: "Medical schools are not interested in students who do nothing but study. They do not consider high grades a just compensation for a paucity of extracurricular activities."

Solomon says he began writing the book during his senior year of college, "after I had attended all my interviews, received acceptances from all but one of the medical schools in which I was interested, and watched as the aspirations of many of my pre-med friends slowly went down the drain."

He points out that it is the disappointment of his friends that served as the impetus for writing the book.

He sums up the book by urging prospective medical students with this poignant advice: "Aim as high as you can, and assess reasonably how high you can aim. Prepare yourself as outlined in this book, become competitive to the point of receiving numerous offers of admission, and you'll be able to ensure at least one acceptance."

Solomon received a B.A. magna cum laude in biochemistry from Brandeis University in 1976, where he was awarded the Snyder prize in chemistry and elected to Phi Beta Kappa. While an undergraduate he was a Westinghouse Science Talent Search scholar.

STANFORD—

Heart disease, the major killer among patients with diabetes, may be related to abnormal fat metabolism (breakdown), according to Stanford University researcher Dr. Gerald Reaven.

The relationship may be particularly applicable to diabetics who do not require daily injections of insulin for their survival, the so-called "insulin-independent" diabetics, said Reaven, head of the division of endocrinology and metabolism at Stanford University School of Medicine.

These patients have abnormally high blood levels of sugar and fats, but their insulin levels are essential normal.

It is thought that their tissues may be resistant to insulin, preventing transport of sugars from the bloodstream, or that the hormone is not otherwise working properly.

Reaven and his associates have found that the livers of insulin-independent diabetics produce abnormally high levels of triglycerides (fat molecules).

Excess triglycerides, in turn, "produce fatty deposits in the arteries, and atherosclerosis (heart disease)," said Reaven.

Reaven reported these findings at a recent meeting of the American Federation for Clinical Research in Carmel, California.

In the study, the researchers measured insulin, free fatty acids, and triglyceride levels in 17 insulin-dependent diabetics, and in 20 insulin-independent diabetics.

Free fatty acids are the building blocks of triglycerides.

Although levels of sugars and free fatty acids were similar between the two groups, the insulin-independent diabetics had higher insulin levels than their insulin requiring counterparts, and three to four times the levels of triglycerides in their blood.

This finding suggests that in the presence of normal insulin and high free fatty acid levels, the liver will produce increased amounts of triglycerides, said Reaven.

"The next step is to find a way to treat these patients," he said.

Losing weight is one way these patients can be helped, since many of them are overweight, said Reaven. In addition, changing the quantity or type of carbohyrates taken in the diet can significantly alter blood levels of glucose and insulin.

The Stanford group recently was awarded a one year, $104,000 grant by the National Heart, Lung and Blood Institute to continue its studies of blood fat metabolism in diabetics.

A local premiere of the new musical "Hosea" will be held Friday, March 30 to benefit Stanford University Hospital's proposed Life Support Training Center.

The show is sponsored by the Palo Alto Rotary Club and will be held at 8 p.m. in the Palo Alto Community Theater.

The proposed center, the first of its kind in California, will help meet the growing demand for training in cardiopulmonary resuscitation (CPR) and advanced life support, according to Dr. Michael Eliastam, director of emergency services at Stanford University Hospital.

CPR may mean the difference between life and death for a heart attack victim, said Eliastam. The basic skills are not difficult to learn, he added, but the techniques must be practiced and reviewed regularly.

The facility will house the mannequins, oscilloscopes and other equipment used in training and practice and would be equipped to handle basic training courses for laypersons as well as advanced life support training for physicians, nurses and paramedics.

"The need for this training center is clear," explained Eliastam. "Both the American Red Cross and the American Heart Association are unable to keep up with the demand for training among the lay public and professional health groups."

Instruction will be provided by faculty members in emergency medicine, anesthesia and cardiology from Stanford as well as by instructors from the community, Eliastam said.

A $10 donation per person is requested at the premiere which includes a wine and hors d'oeuvres reception with the show's writer, director and cast members before the performance.

For reservations and tickets, call Jack Pluth of the Rotary Club at Widemans in Palo Alto, phone 328-4170.

"Multiple Sclerosis--1979" will be discussed Thursday, March 22, at Stanford University Medical School by Dr. Guy M. McKhann.

The address, open to the medical community and the public, is the third annual George A. Zimmermann Lecture. The talk will begin at 5 p.m. in Room M-106.

McKhann, a former faculty member at Stanford, is Kennedy professor of neurology and neurologist-in-chief at The Johns Hopkins University School of Medicine in Baltimore, Md.

McKhann was associate professor of medicine at Stanford before leaving in 1969 to join Hopkins. He received his M.D. from Yale Medical School in 1955.

Much of his research was started at Stanford and continued at The Johns Hopkins, including methods of judging and diagnosing multiple sclerosis, and isolation of cells for the study of neurologic disease.

Multiple sclerosis, or MS, is a disease marked by patches of hardened tissue in the brain or spinal cord, often involving partial or complete paralysis and jerking muscle tremor.

The Zimmermann Lectureship was established in 1977 by the Department of Neurology at Stanford Medical School. The lecture is part of a $500,000 gift by the late George A. Zimmermann for multiple sclerosis research and treatment at Stanford.

A longtime San Francisco businessman, Zimmermann died in 1974. He bequeathed virtually all of his estate to various charities and for medical research.

STANFORD—

Motivation is the prime ingredient for youthfulness, especially in old age, according to Dr. Russel V. Lee, professor emeritus of medicine at Stanford University School of Medicine.

"I retired at age 65, but I didn't stop," said Lee Wednesday night, March 14. "In the first three years of my retirement, I made $5 million, more than I had made in over 50 years of medical practice."

Lee is well known as founder of the Palo Alto Medical Clinic, and as an often controversial advocate of group practice, prepaid health insurance, and Medicare.

Now 83, he continues to play an active role in the community. He helped establish the Palo Alto Medical Research Foundation, and Channing House, a retirement apartment complex near the clinic, "after I was supposed to be senile and retired," he said.

"People should never 'retire,' " he said. "I never intend to. I begin each year preparing for the future.

"My present ambition is to lose a paternity suit," he added with characteristic wit.

Lee spoke to about 500 people at the final lecture in the Progress in Medicine series on aging, sponsored by the School of Medicine and the Medical Center Council.

He was joined by Dr. Leo Hollister, professor of medicine, psychiatry, and pharmacology, and director of psychopharmacoloy research at the Palo Alto Veterans Administration Medicial Center.

Lee credited advances in medicine during the last 30 years for much of his longevity.

"When I came to the Stanford campus in 1918, the principle cause of death in the United States was tuberculosis," he said. "We don't even list it anymore."

The discovery of insulin made it possible to save the lives of diabetics. And the discovery of antibiotics wiped out other infectious diseases.

Syphilis and gonorrhea are still prevalent, however. Lee noted that during the last 10 years, 25 percent of local high school girls have had venereal disease.

With effective drugs like penicillin around, the continued presence of venereal disease in this country is "an insult to human intelligence," he said.

Today, the major disease killers, such as heart disease and cancer, are those which come with the process of aging.

But even these can be avoided, said Lee. A lean diet, adequate exercise, and avoidance of known cancer-causing agents all help people live long and healthy lives.

"We know that tobacco is a lethal substance," he said. "Anyone in this day and time and in light of what we now know who still smokes is either illiterate or despondent."

As medicine continues its progress, and life styles improve, more and more people are becoming old, said Lee.

In 1900, only four percent of the U.S. population lived to be 65. This year, that figure is 15 percent, and by the year 2000, Lee estimated, over 50 percent of the population will be over 65.

"I venture to say that we'll have 50 million 100-year-olds in the U.S. by the year 2000," he said.

"I'd like to live long enough to see if my prediction was right."

Lee said that dealing with these people is a very serious matter for society.

-more-

But they can have a place. Some of the residents of Channing House, for example, have been teaching persons half their age to read and write.

Older persons can be artists, and poets. They have the patience for these tasks that younger people don't, he said. Lee noted Grandma Moses, the famous painter, and his former Stanford professor, the bacteriologist Dr. Hans Zinsser, who wrote a book of poetry in his later years.

Lee himself is the author of several books, including *No Gravy on the Vest,* about "the art of growing old in style."

Older people also continue to have a valuable role in the family, said Lee, who calls himself a strong proponent of the "old-fashioned" family. Lee's five children all followed his lead and received their medical doctorates. Two of them practice at the Palo Alto Medical Clinic.

Old age can be very good, said Lee. "I find this period of old age has been enormously pleasurable for me. I wake up every morning glad to be alive."

STANFORD—

A group to develop a long-range plan for the continued development of the Stanford University Medical Center has been appointed by Acting Vice-President and Dean Lawrence G. Crowley.

"A basic issue that must be addressed is how can the Medical Center maintain its excellence and continue to develop as a major academic medical center in the 1980s," said Crowley.

"This effort," he added, "is especially important in light of emerging economic and social pressures, changing health care delivery systems at national, state and regional levels, and altering goals, sources and mechanisms for financing of medical education and biomedical science."

Crowley noted that planning is already underway by the Hospital to correct its major physical deficiencies stemming from new code requirements and standards for hospitals.

"Before the final selection among the correction options is made, it is important that the entire Medical Center develop a long-range strategic plan based upon a full review of its current programs and a sound analysis of potential future programmatic initiatives," he said.

Recommendations of the group will be reviewed by the administration of the Medical Center and University, the executive committee of the School, and the board of hospital directors.

The group will be chaired by Crowley with Peter J. Levin as vice-chairman. Levin is associate vice-president for medical affairs and executive director of Stanford University Hospital and Clinics.

Members include Paul Berg, professor of biochemistry; Robert A. Chase, professor of surgery; Alain C. Enthoven, professor of public and private management, Stanford Graduate School of Business; Maurice Fox, Palo Alto Medical Clinic physician, and clinical assistant professor of medicine; Kenneth R. Hansen, consulting economist and member, Hospital board of directors; Henry S. Kaplan, professor of radiology; David Korn, professor and chairman, Department of Pathology; Kenneth L. Melmon, professor and chairman, Department of Medicine; and James H. Stanford, director of Medical Center Finance.

STANFORD—

The panel charged with overseeing recombinant DNA research at Stanford University recently added two members from the community to its ranks.

Dr. David Rammler and Dr. Robert Stephens have been appointed by university president Richard W. Lyman to the Stanford University panel on recombinant DNA molecules. They join Dr. Richard Rosenbaum as panel community members.

Guidelines concerning the conduct of federally funded recombinant DNA research issued by the Department of Health, Education and Welfare were revised recently. One change requires institutional biosafety committees overseeing gene-splicing research to have not less than 20 percent of their members "represent the interest of the surrounding community with respect to health and protection of the environment."

Rammler is director of new technologies at Syntex Corporation in Palo Alto, Rosenbaum is an engineer with Lockheed Missiles and Space Company and Stephens is manager of the cellular biology program at SRI International in Menlo Park.

According to Andrew Doty, director of community relations at Stanford, "we looked for people with a track record of defending community interests, a record of civic activities and an ability to make objective judgements concerning the university."

Stephens is a former mayor and a council member in Menlo Park. Rosenbaum is a former city council member from Palo Alto.

The panel meets once monthly according to Anthony Sidlow, manager of health and safety at Stanford, with every fourth meeting open to the public. Minutes from the meetings are available at Lane Medical Library and at Meyer Undergraduate Library on campus, he added.

The panel has 15 members who are appointed to renewable one-year terms, with a maximum tenure of three years, Sidlow said.

Three ex officio members representing the medical center and university safety offices and the sponsored projects office also sit on the committee.

Duties of the committee include reviewing and approving recombinant DNA research proposals, reviewing physical facilities, monitoring research projects conducted at Stanford, adopting emergency plans in case of accidents, and reporting any problems with guideline compliance to HEW.

The other committee members are Ronald Davis, associate professor of biochemistry; Marianne Dieckmann, research associate in biochemistry; Wray Huestis, assistant professor of chemistry; John Kaplan, professor of law; and Roger Kornberg, professor of structural biology.

Also, Perry McCarty, professor of civil engineering; David Perkins, professor of biological sciences; Burton Richter, professor at SLAC; Nathan Rosenberg, professor of economics; Robert Simoni, professor of biological sciences and panel chairman; Dave Thom, undergraduate in human biology; and Charles Yanofsky, professor of biological sciences.

Ex officio members are Edward Barrera from the office of sponsored projects; Jean Bernard from the medical center's health and safety office; and Anthony Sidlow, university manager of health and safety.

STANFORD—

Stanford University School of Medicine expects to sustain a $290,000 operating budget deficit, and a $400,000 deficit in the faculty practice budget in 1979-80.

This is the forecast based on the Operating Budget Guidelines for the coming year approved by the Stanford University Board of Trustees, Tuesday, March 13.

The deficit can be met by the Medical School's own reserves. The School is currently engaged in a two-year effort to restore budget equilibrium.

The process, according to Acting Vice President and Dean Lawrence W. Crowley, will focus on clarifying each department's programmatic missions and determining those activities which are most essential and those which are least essential.

In addition, certain School-wide initiatives aimed at reducing expense are under consideration.

In accord with the federal government's wage-price guidelines, the budget document anticipates an increase in faculty and staff salaries at a cost of about $765,000 including benefits.

Funding of presently unfilled faculty positions, including support costs, would require about $600,000.

Other highlights include:

• Maintenance, security and custodial services are expected to increase by $200,000 in line with salary adjustments.

• Utilities will be increased $425,000 because of new University charges; the rate of utility inflation is expected about 9 percent, with total utility costs up about $540,000.

• About $150,000 per year of new utility and maintenance costs will be added with the opening of the third floor of the Sherman Fairchild Building now under construction.

• Library acquisition costs, expendable materials and services, and other non-personnel categories of expense will be about $350,000.

The School of Medicine is fully responsible for operations and maintenance of its facilities. Its budget relates to the operating costs, faculty medical practice which produces professional income, restricted funds such as government grants and contracts, and costs associated with activities performed by School personnel in the hospital.

The 1978-79 total budget is $73.5 million.

Long-range forecasts by the Medical School in 1978 predicted a mounting deficit in the combined operating and faculty practice budgets next year if no action were taken. This is primarily the result of new regulatory interpretations by Medicare and Medi-Cal.

While, according to the document, the exact impact may not be known for some time, it is clear that the amount ultimately received will be significantly reduced if not lost entirely.

Consequently it "must be regarded as conditional income not available to meet ongoing operating needs," the document said. However, sufficient Medical School reserves exist to cover projected deficits.

STANFORD—

Stanford researchers have compiled a library of the normal magnetic tracings in the human heart, and they believe these readings may lead to a more accurate diagnosis of heart disease.

The library was introduced Monday, March 12 before the American College of Cardiology in Miami.

Dr. Jerry Griffin, acting assistant professor of cardiology, and Mark Leifer, graduate student in applied physics, presented the data which they and cardiology fellow Dr. Richard Meltzer began recording last August.

"Now that we have defined normal we can identify readings that indicate an abnormal state," Griffin explained.

The researchers used a differential magnetometer to record the normal heart. This device, which can pick up tracings one million times weaker than the earth's magnetic field, measures the magnetic field produced by charged particles flowing through heart muscle cells. It also cancels out other environmental magnetic fields that would interfere with the heart readings.

Before developing the differential magnetometer, researchers had no way of subtracting these environmental magnetic readings from those of the heart. In order for researchers to obtain fairly precise tracings, patients were lowered into a 25-foot well lined with magnetic shielding.

The differential magnetometer was built in 1977 by the S.H.E. Corporation of San Diego. It is currently at Vanderbilt University in Nashville, Tenn. where it is used by Dr. John P. Wikswo, Jr., who helped design it while he was at Stanford as a graduate research associate in physics.

"It is now up to the cardiologists to put the physicist's work to practical use," Griffin said.

In diagnosing some heart diseases, the magnetometer may be more effective than the electrocardiogram (ECG) which measures the flow of electricity through the heart. For example, abnormalities in cardiac impulse conduction can be detected by an ECG but may be more evident in the magnetocardiogram.

Conduction disorders cause the heart to beat irregularly and are sometimes fatal.

The magnetometer can also identify areas where normal conduction has been hampered as a result of a heart attack or an injury, Griffin said.

In addition, the magnetometer may be more efficient than the ECG in helping physicians diagnose emphysema and other diseases involving air, fat or fluid insulators around the heart.

Because both techniques can sense information that may be fully or partially hidden from the other, Griffin believes the magnetocardiogram will never replace the ECG, but only complement it.

"Unfortunately there is probably some information that is not being picked up in either technique," he said.

According to Dr. Donald Harrison, director of the research project, mass screening of cardiac problems would be easier with the magnetometer because it is a completely noninvasive device. ECGs require the attachment of electrodes to the patient's body.

"It's a thought for the future," Griffin agreed. "But we still need several more years of experiments and analysis of the magnetometer before it can be utilized on a wide scale."

STANFORD—

"Growing Old Gracefully," the third and final public lecture in the current Progress in Medicine Series, will be presented Wednesday, March 14, at Stanford University School of Medicine.

Speakers will be Dr. Russel V. Lee and Dr. Leo E. Hollister.

Lee is clinical professor of medicine, emeritus, at Stanford, and founder of the Palo Alto Medical Clinic. Hollister is professor of medicine, psychiatry and pharmacology, and director of psychopharmacology research at Veterans Administration Medical Center in Palo Alto.

The lecture is free and begins at 7:30 p.m. in Sherman Fairchild Auditorium.

This Progress in Medicine Series has been titled "The Coming of Age," and has featured a series of talks by Stanford physicians on the physical and emotional aspects of growing older.

In 1976 Lee authored the book, *No Gravy On The Vest*(subtitled "The Art of Growing Old in Style"), in which he examines his life, including the five decades spent as a practicing physician. He also writes about health and illness, and the vast spectrum of problems associated with aging. But, he also advises his readers on what they can do for themselves both physically and emotionally in order to enjoy a fuller, more rewarding life during the later years.

As he writes in his introduction, "I hope to show that these later years can be the best of life."

Hollister is an internationally recognized researcher in clinical pharmacology. For years he has researched the similarities between basic pharmacology of psychoactive drugs and their clinical use, and has been one of a few scientists to successfully bridge the gap between research and therapy.

Hollister pioneered methods of patient selection and data analysis necessary for scientific clinical research with psychotherapeutic agents. Furthermore, he has made important contributions to the understanding of certain drugs, particulary marijuana, and their treatment when abused.

His book, *Chemical Psychoses, LSD and Related Drugs* (published in 1973), is considered a definitive work on the subject. It represents two decades of clinical experience and experimentation with psychotherapeutic drugs. The book is considered recommended reading at many medical schools.

Mime, the classic theatrical art form based on stories without words, will be presented by Pianomime in a benefit performance Saturday, March 17, for the Premature Infant Research Fund at Stanford Medical Center.

The performance will begin at 8 p.m. in the Little Theater on the Stanford campus. Tickets are $3.50 each and are on sale at Stanford's Tresidder Box Office. Tickets will also be available at the door.

Pianomime is an amateur troupe of eight members. It was formed in 1975 by Stella Bensadon, a mime instructor. She is a performer in the troupe, along with Lisa Pincus, Peter Lelieveld, Kazuko Yamamoto, Jeff Cibili, Dolores Harrison and Helene Davis. Pianist is Dave Gollub.

The troupe has had many area performances, and in 1976 it presented a similar benefit performance for Stanford's Premature Infant Research Fund. Several members of the troupe performed at Stanford's annual Christmas Faire last December.

Several of Pianomime's members have performed in foreigh countries. Bensadon, for example, is a former student of the wife of Marcel Marceau, as well as Etienne Decroux. Cibili has likewise performed abroad, including Venezuela (where he was on Caracas television), Brazil, France, Puerto Rico and Mexico.

Pianomime's next performance will be Friday, March 23, at the Palo Alto Cultural Center, also beginning at 8 p.m.

STANFORD—

Two common diseases of the elderly, arthritis and osteoporosis, a gradual depletion of bone, may be slowed by controlling diet and exercise, two Stanford University physicians said Wednesday night.

A combination of pain-killing and anti-inflammatory drugs with a program of exercise are the major tools currently available in treatment of arthritis, said Dr. Thomas B. Okarma, staff physician in the division of gerontology.

However, recent discoveries on the causes of arthritis may lead to more effective treatment of the disease, he suggested.

Arthritis afflicts 85 percent of the population over 75, Okarma reported, and the extra amount of mobility resulting from a planned exercise program can make the difference between an independent life and institutionalization, he said.

It is important to break the debility cycle, he said, where pain encourages the individual not to use the joint, causing muscle atrophy from disuse and further immobility and pain.

In arthritic disease, cartilage, the "shock absorber" between bones the body's joints, is destroyed, explained Okarma.

Because cartilage lacks nerves, an individual may not be aware of its destruction until the cartilage is all gone, and bone rubs bone.

The pain associated with arthritis is caused by trauma, swelling or inflammation in association with cartilage breakdown.

The key to future control of arthritis is the recent discovery that one of our normal body enzymes is responsible for the initial breakdown of cartilage.

"We don't yet know what triggers this enzyme's destructive action," said Okarma, "but current research is focused on looking for substances which will inhibit the enzyme's action, and prevent the initial cartilage breakdown from occurring."

Osteoporosis is "the end result of a gradual depletion of bone which begins early in life," explained Dr. Robert A. Marcus, assistant professor of medicine.

Bone depletion leads to pain, fractures and deformity. "It's a public health problem of major proportions," he said, and effective therapy can't be initiated after the fact.

"We must identify susceptible individuals and help control the risk" with proper exercise and dietary calcium, he said.

Marcus described how osteoporosis occurs. Bone serves several functions in the body, he explained. It is a weight bearing support, and it is also the body's reservoir of calcium, drawn on in times of need when insufficient calcium is present in the blood.

-more-

The concentration of calcium in body tissues is regulated by several organs in the body, and is under the control of parathyroid hormone.

"The concentration of calcium in the blood is so crucial that it can be taken from bone when needed, even at the cost of sacrificing the bone itself," Marcus stressed.

This illustrates why inadequate amounts of calcium in the diet may lead to osteoporosis or bone mass depletion, Marcus explained.

From age 50 on, both sexes experience this loss of bone. However, men start out with a higher bone density and so are relatively free from debilitating osteoporosis, he said. Blacks also have a high initial bone density and do not frequently experience the disease.

"Thin white women who smoke" are in the highest risk group for serious osteoporosis, Marcus said. Because osteoporosis cannot be detected with x-rays in its early stages, knowing the factors which limit progression of the disease may be the best way to stave off a severe affliction, he said.

Physical activity helps maintain bone density, Marcus said. Even simple walking late in life is beneficial.

Diet also plays an important role. Marcus noted tha the minimum daily recommended allowance of calcium is 800 milligrams but recent evidence suggests that women entering menopause need up to 1200 milligrams, or close to the amount of calcium contained in one quart of milk.

A complicating dietary factor is revealed in studies of animals, Marcus said, where optimum bone strength was obtained when calcium and phosphorus were available in the diet in equal quantities. When phosphorus intake was increased, the bones weakened.

"We are a phosphorus consuming society," cautioned Marcus. Meats have phosphorus, he said, and unless prepared in stews with the bones, meats have relatively little calcium. Dairy products contain equal amounts of calcium and phosphorus, he said, and soda drinks are very rich in phosphorus.

For high risk people who cannot tolerate dairy products, Marcus advised eating calcium rich foods such as bean curd, stews prepared with bones, shrimp, crab and almonds.

Estrogen therapy may reduce bone mass decay, according to recent evidence, Marcus reported, but the risks of such therapy must be balanced against the benefits with the help of a physician, he suggested.

And although the connection between smoking and osteoporosis is not understood, Marcus noted that women who smoke are at greater risk than those who don't.

Okarma and Marcus spoke before a capacity crowd in Fairchild Auditorium at the second evening of the Progress in Medicine lecture series on aging sponsored by the school of medicine and the medical center council. The last lectures in this series will be held at 7:30 p.m. in Fairchild on March 14. Drs. Leo Hollister and Russel Lee will discuss "The experience of age: sexuality, mood and other emotions."

STANFORD—

The vastness and organization of the Chinese population provide "exciting opportunities" for international cooperative research on the causes and treatment of cancer.

That is the concensus of a group of U.S. cancer specialists after a visit to China in 1977.

Their findings have recently been published as a book, entitled *Cancer in China* (Liss, New York, 1978), edited by Dr. Henry S. Kaplan, D'Ambrogio professor of radiology at Stanford University, and Patricia Jones Tsuchitani, of the National Academy of Science's Committee on Scholarly Communication with the People's Republic of China.

The 24-day visit by the U.S. delegation was cosponsored by the Committee and representatives of the Chinese government.

The strong point of the Chinese cancer effort is in early detection and prevention of disease, reported the American observers.

"According to Chairman Mao Tse-tung's teachings, in medicine as in other fields, emphasis should be placed on activities for the masses, especially peasants, with special attention to prevention," said delegate member Dr. I. Bernard Weinstein, professor of medicine at Columbia University.

"Mass surveys for health care come naturally to the Chinese, and they undertake such screenings, sometimes involving skillful maneuvers, on large numbers of people."

For instance, in Shanghai, 690,000 vaginal smears have been done among textile workers since 1958, uncovering cancers of the uterine cervix in the early stages.

"Deaths from this form of cancer among textile workers have been virtually eliminated," the group was told, largely because of early detection.

The Chinese are also making impressive gains in early detection and treatment of cancer of the esophagus, a 2000-year-old disease that strikes a greater proportion of people in the northern Linshien County than anywhere else in the world.

In particular, they have "come close to identifying a natural carcinogen (cancer-causing agent) in certain foods," stated the delegates.

The people of Linshien County commonly eat a mulch of vegetables which has been stored at room temperature and is covered with mold.

The mulch is very acidic. Acidic conditions permit conversion of the high levels of nitrates and amines found in the soil and water of the region into nitrosamines, potent cancer-causing agents in laboratory rats.

High rates of esophageal cancer are also found among the chickens of these people, which are fed the mulch.

-more-

Further support to the theory comes from a study of 50,000 workers who had moved 360 miles away from the region. Despite the change in environment, they continued to have high rates of cancer, and continued to eat the mulch.

Moreover, the chickens they brought with them began to develop esophageal cancer, apparently from their diet of table scraps.

As for diagnosis and treatment, the Chinese have "improvised effectively techniques for mass screening and educating the public to take measures to prevent cancer or detect it early," reported the delegation.

Early diagnosis of esophageal cancer is done by having patients swallow a mesh-wrapped balloon and then pulling it back through the throat. The mesh scrapes mucous membrane off the esophagus which is then examined under the microscope for the presence of cancer cells.

This approach, combined with surgical treatment, achieved a five-year survival rate of 43 percent in one group of 1300 patients.

Progress in treating other cancers is not as dramatic, however.

Cancer of the lung is the number two cancer killer of both men and women in China, just behind stomach cancer.

The incidence of lung cancer has doubled in Shanghai in the last decade, and is paralleled by a rapid increase in cigarette smoking since the late 1940s.

Yet the Chinese emphasize early detection, rather than prevention of this disease.

"Indeed, cigarettes were routinely offered with tea at all but one of the major hospitals" visited by the delegates, "and smoking by males, especially young adults, was excessive."

There are 11 cancer hospitals in China, compared with only one 20 years ago.

The delegation found the surgical suites were immaculate and well-lighted, if sparsely equipped. The surgeons were well-trained and expert.

However, radiation departments are constrained by out-dated equipment, lack of trained personnel, and enormous caseloads, they reported.

An average clinic may treat as many as 500 patients per day, in multiple shifts around the clock, using equipment which is 20 years old.

Both Western and Chinese herbal medicines are employed in chemotherapy, and currently, the Chinese are determining the cancer-fighting ingredients of many herbs used to treat the disease.

Acupuncture is used as anesthesia prior to surgical removal of tumors, but only very selectively.

Although familiar with the Western clinical trials as a means of testing new therapies and techniques, the Chinese must still be convinced of their importance, said Kaplan.

"The design and conduct of randomized clinical trials could perhaps be more effectively and readily implemented in China than elsewhere," he said.

"The improved regimens stemming from such clinical investigations would benefit cancer victims throughout the world."

FOR IMMEDIATE RELEASE

STANFORD—

Associate Prof. Zoltan J. Lucas of the Stanford Department of Surgery has been officially reprimanded by President Richard W. Lyman and suspended for 12 weeks without pay for professional misconduct in his research work.

The suspension took place March 5 and will run to May 25.

A specialist in transplantation immunology, Dr. Lucas has admitted that 18 citations of his scientific papers were in error between 1967 and 1977.

In 10 instances the papers he cited concerning his work already had been rejected. In five instances they had never been submitted for publication. In three, the wrong journal was cited.

An internal study completed by the University last August concluded there was "persuasive evidence" that five other citations by Dr. Lucas concerning his own work were in error.

A complete review of Dr. Lucas' citations was made after a 1977 study showed errors in eight out of 10 citations of scientific papers had been made by Dr. Lucas in grant applications to the National Institutes of Health.

"Repeated reporting of inaccurate citations, be it careless or intentional, constitutes serious professional misconduct and warrants sanctions," former Vice-President Clayton Rich and Vice-Provost Gerald Lieberman told Lyman.

"The fact that this inaccurate reporting occurs over a period of many years, coupled with the conclusion that Dr. Lucas knew or should have known of these inaccuracies, argues for a very substantial sanction."

Allegations of scientific impropriety in Dr. Lucas' research were reviewed in 1975 by faculty members, who concluded there were deficiencies in his teaching, research, and laboratory management.

In November 1977 James W. Schriver of NIH wrote Rich asking for an investigation of allegations by Dr. Eugene Dong of the Stanford Medical School concerning apparent discrepancies in tables submitted by Dr. Lucas in an NIH contract proposal and other documents.

An independent review of these allegations concluded one error was due to oversight without intent to misrepresent data while another, at minimum, represented a failure to meet acceptable standards in transcribing and editing scientific data.

-more-

Replying to another inquiry from NIH, prompted again by Dr. Dong, Dr. Lucas conceded last April there were three errors in a research table describing his work in an applicaton to NIH in 1972.

"There has been no conclusion that your research results have been seriously affected," Lyman told Dr. Lucas. "The trouble with carelessness in research, however, is that one has no way of knowing when it may have devastating consequences. . . .

"Because of the chronic nature of your professional misconduct and incompetence over a period of many years, the University must exercise some prospective controls to ensure that your behavior in this respect is not continuing."

For this reason, after two years, the head of surgery and the Medical School dean will conduct a formal review of Dr. Lucas' research, including experimental design, recording, and reporting of data and publications.

A finding of either professional misconduct or substantial and manifest incompetence at the end of this period could result in separation from the University.

Lyman said the University plans to make a comprehensive report of its findings and actions to the NIH without delay.

Lucas holds a degree in biochemistry from MIT and an M.D. from Johns Hopkins. After interning at Barnes Hospital, St. Louis, where he specialized in surgery, he joined Washington University's Department of Molecular Biology as an NIH fellow.

He continued research work in molecular biology at Stanford during 1963-65, then taught at Duke for two years before returning to join the Stanford faculty.

While suspended from the University, Dr. Lucas may not continue as a principal investigator on research projects. He currently holds both a contract and a grant from the National Cancer Institute and a grant from the American Cancer Society. Both are being notified of his suspension.

While suspended, Dr. Lucas may not participate as a faculty member in any departmental, school, or University bodies or have access to office space, laboratories, or other facilities not open to the public. this does not include Lane Medical Library.

During his suspension Dr. Lucas will not have practice privileges at Stanford Hospital as a faculty physician but he may apply for staff privileges as a nonfaculty physician.

STANFORD—The second in a series of public talks by Stanford physicians on the physical and emotional aspects of aging will be presented Wednesday, March 7, at Stanford University School of Medicine.

Drs. Thomas B. Okarma and Robert A. Marcus will discuss "Aches and Pains," or what happens to the bones and joints in humans as they grow older. The address begins at 7:30 p.m. in Fairchild Auditorium at the medical school.

The lectures are part of the medical school's Progress in Medicine Series. This particular series is being cosponsored by Veterans Administration Medical Center in Palo Alto in association with the Medical Center Council.

In all, six lecturers are featured in this series, which is entitled 'The Coming of Age."

Okarma is staff physician, and Marcus assistant professor of medicine, both in the Division of Gerontology.

The third and final lectures in this series will be presented Wednesday, March 14, by Drs. Leo Hollister and Russel V. Lee on "Growing Old Gracefully." Hollister is professor of medicine, phychiatry and pharmacology, and director of psychopharmacology research at V.A. Lee is clinical professor of medicine, emeritus, at Stanford, and founder of the Palo Alto Medical Clinic.

STANFORD—Dr. James Silverman has been appointed chief of staff of the Stanford University Hospital and associate dean for clinical affairs, acting Vice President for Medical Affairs Dr. Lawrence G. Crowley announced Friday, March 2.

Currently the clinical director of diagnostic radiology, Silverman succeeds Crowley, who became acting vice president and dean of the Medical School January 1 after the resignation of Dr. Clayton Rich.

"Dr. Silverman is an experienced clinical radiologist who has shown an excellent grasp and understanding of patient care issues throughout the hospital," said Crowley.

"He has also exhibited strong leadership qualities and we are looking forward to his joining the professional administrative leadership of the hospital and school."

His duties include coordinating the activities of the chiefs of service and the medical directors of special units, advising the dean on hospital clinical matters, and directing the hospital professional standards and quality assurance programs.

In an interview, Silverman said his primary goal will be to improve communication between the medical staff and the administration.

"The biggest challenge we face is to bring together all of the medical community as a viable and equal group," he said. "They should all feel secure and believe they have a voice in the future affairs of the hospital.

"The hospital will flourish only if the whole medical community is behind it."

In addition to his position in diagnostic radiology, Silverman is chief of the cardiac radiology section, co-director of the cardiac catherization laboratories, and associate professor of clinical radiology in the Medical School.

He also participates in several hospital activities, including the quality assurance, credentials, and ambulatory care committees.

Improving communication has long been one of Silverman's goals.

Recently, he and his associates in diagnostic radiology inaugurated a new reporting system. It is designed to transmit rapidly important clinical information, "while retaining the successful teaching method of the diagnostic radiology residency program which is one of the most sought after in the country," said Silverman.

The group is now working on a computerized coronary arteriogram reporting system which will enable referring physicians to review graphic reports within hours after the studies are completed.

A native of Pittsburgh, Pa., Silverman received his medical doctorate in 1961 from Philadelphia's Hahnemann Medical College. After four years in general medical practice, he returned for training in diagnostic radiology.

He served as a cardiovascular fellow at Stanford in 1970, and joined the medical staff the following year.

In 1978, Silverman was a Sloan Fellow at the Stanford Graduate School of Business, and received his masters degree in business management.

The first physician to complete this program at Stanford, Silverman said he felt the training would be invaluable in his new position.

STANFORD—Scientists may be able to alter the aging process within the next 100 years, according to Stanford University gerontologist Dr. Lawrence M. Crapo.

"The implications of being able to extend the human life span are staggering, to say the least," said Crapo.

Crapo, assistant professor of medicine, and Dr. Gerald M. Reaven, head of the division of gerontology at Stanford, spoke on the biology of aging Wednesday night to an overflow crowd of about 600 people at the Medical School's Fairchild Auditorium.

The lecture was the first of three in the Progress in Medicine series on aging sponsored by the School of Medicine and the Medical Center Council. The remaining lectures will be delivered Wednesday nights, March 7 and 14 at 7:30 p.m. in Fairchild Auditorium.

People throughout the ages have sought various elixirs, however, the maximum human life span has remained fixed at about 100 years since antiquity, said Crapo.

Neither diet, nor life-style, nor even modern medicine can extend life much beyond the 100 year mark, he said.

Medicine has helped to markedly increase human life expectancy at birth, said Crapo, but "any future progress in this area can only come from an understanding of the process of aging."

For instance, if all cancer was eliminated, life expectancy would increase only two years. Eradicating all heart disease would add eight or nine more years.

This is not to say cancer and heart disease should not be eliminated, said Crapo, for with them would go a lot of human suffering.

But it means that even if all disease was eliminated, people would still die.

The secret to aging lies in the genes, said Crapo.

In the 1960's, Dr. Leonard Hayflick, former professor of medical microbiology at Stanford, demonstrated that normal human body cells age when grown in the test tube.

"They seem to have a fixed, finite life span of about 50 doublings," said Crapo.

This phenomenon, known as the Hayflick limit, has been verified in hundreds of laboratories. "It is the prototype for human aging at the cellular level," said Crapo. "Aging may be intrinsic to cells."

Tissues also demonstrate aging. When skin from an old rat is transplanted to a young rat, the skin retains its original age, that is, it decays and dies while the young rat lives on, said Crapo.

Other evidence for the genetic role in aging comes from rare, so-called rapid aging syndromes, in which children exhibit some of the characteristics of very old persons, such as wrinkled skin and atherosclerosis. They usually die at an early age from heart attacks or strokes.

-more-

Recently, two researchers in England, R. Holliday and T.B.L. Kirkwood, have presented an alternative to the Hayflick limit theory, said Crapo.

They suggest that not all cells grown outside the body age at the same rate. Some may live beyond 50 doublings. Their hypothesis has not yet been proven.

While investigators attempt to determine the cellular basis for aging, others are focussing attention to the genes.

Two theories attempt to explain how and why cells age. In the first theory, aging is programmed in the genetic material of the cells, just as fetal development is. When the cellular machinery reads the instructions encoded in the genes, development and aging occur.

However, there is no data to support this theory, said Crapo, and it is questionable that natural selection would have chosen a genetic program which leads to death of the organism.

The second theory maintains that aging results from an accumulation of errors in the production of proteins from the genes. Proteins produced by error eventually lead to an "error catastrophe," said Crapo, and cell aging.

The production of errors is thought to be a natural process which allows organisms to adapt to changes in their environment.

According to the theory, "cell machinery is error prone," said Crapo. "It had to be for us to survive. The price we pay is aging, because errors accumulate.

"Aging thus results from what we are, and is part of life. But that is something we know already."

If this theory is correct, scientists may be able one day to alter the aging process, with gene manipulations aimed at preventing the accumulation of errors, said Crapo.

Reaven's talk concerned patient care, teaching and research in the division of gerontology and at the Geriatric Research Education and Clinical Center, located at the Palo Alto Veterans Administration Medical Center (VAMC).

The center, directed by Reaven, conducts research into diseases which occur more frequently among older people, and provides training for medical students, resident physicians, postdoctoral fellows and outside health professionals.

In addition, a new 12-bed clinical unit specifically designed to study problems unique to aging is being planned, said Reaven.

"We also plan to establish a model outpatient clinic at the VAMC, to provide medical care for older individuals and medical training. It will enable us to evaluate ways of providing the best possible care," he said.

Reaven is well known for his studies of carbohydrate and lipid metabolism as it relates to diabetes and atherosclerosis.

He and his associates have found a relationship between the decline in the body's ability to absorb sugars from the blood which occurs with age, and a defect in the secretion of insulin.

"We have defined a very basic defect in insulin secretion associated with aging," said Reaven. "This doesn't prove that a lack of insulin is the cause of high levels of blood sugar in the older individual. The insulin itself may not function normally."

(Editors: Although this program is to be aired nationally by PBS on May 6, some stations may show it at different times and dates. KQED-TV, Channel 9, in San Francisco, will broadcast it on Saturday, May 26, from 9:30 to 10:30 p.m. It will be repeated on San Francisco's Channel 32 (UHF) on Sunday, May 27, from 10:30 to 11:30 p.m.)

STANFORD—

"Being Human," an hour-long documentary focusing on what sets the human species apart from other creatures will be televised by the Public Broadcasting Service (PBS) on Sunday, May 6, from 2 to 3 p.m. (EDT).

This special documentary is the first to be produced for the general public by the Office of Postgraduate Education at Stanford University School of Medicine. The program features the views of 16 accomplished artists and scientists.

The program was written and produced by Dr. Edward Rubenstein, professor of clinical medicine and associate dean of postgraduate medical education.

Participants in the production are Judith Blegen and Frederica von Stade of the Metropolitan Opera; Norman Cousins, author and editor of*Saturday Review;* Dr. David Hamburg, president of the Institute of Medicine of the National Academy of Sciences (and currently on leave of absence from the Stanford faculty); Dr. Robert Hofstadter, physicist and Nobel laureate at Stanford; and vocalist Ella Fitzgerald.

Also, Dr. Rene Dubos, biologist at Rockefeller University; Dr. Philip Handler, president of the National Academy of Sciences; concert violinist Yehudi Menuhin; Dr. Joshua Lederberg, Nobel laureate and president of Rockefeller University; sculptor Henry Moore; Dr. John Nicholls, neurobiologist at Stanford; Dr. Linus Pauling, Nobel laureate and director of the Linus Pauling Institute for Science and Medicine; Ava Helen Pauling; concert pianist Arthur Rubinstein and Mrs. Arthur Rubinstein.

Editor's:—Photographs of Drs. Nicholls, Dewson and Prince are available if not included with the release.

Recent medical findings involving the human brain will be discussed by three Stanford neuroscientists in the spring Progress in Medicine Lecture Series on successive Tuesdays May 2, 9, 16 at Stanford University School of Medicine.

Drs. John G. Nicholls, David A. Prince and James H. Dewson will present the public lectures, each of which begins at 7:30 p.m. in Fairchild Auditorium of the medical school.

Nicholls, who is professor of neurobiology, will give the first lecture May 2 entitled "From Nerve Cell to Brain," or how individual nerve cells contribute to the workings of the brain.

On May 9 Prince will discuss "The Brain as an Imperfect Machine." His talk will center on advances in understanding epilepsy and other brain disorders. Prince is professor and chairman of the Department of Neurology.

"How do Monkeys' Use Their Heads?" will be the subject of the address May 16 by Dewson. The talk will highlight studies of monkeys' abilities to remember what they've heard. Researchers have found similarities in the left-right organization of the human brain.

Dewson is associate professor of speech and hearing sciences in the Department of Surgery, and acting director of the Division of Laboratory Animal Medicine.

Nicholls is considered one of the country's leading neurophysiologists. He joined the Stanford faculty in 1973.

Co-author with S. W. Kuffler of the book *From Neuron to Brain--A Cellular Approach to the Nervous System,* Nicholls is an adjunct fellow at the Salk Institute in La Jolla and the advisory board of the National Paraplegia Foundation.

Prince is a widely-recognized researcher of epilepsy, a disease in which the victim suffers seizures or convulsions due to abnormal brain activity.

Last year he was awarded the Lennox Prize by the American Epilepsy Society for his contributions in the field.

Dewson's research with monkeys led to the discovery in 1976 that these primates possess a type of brain which had earlier been associated with man's specific intellectual capacities.

Prior to that, researchers had generally determined that monkeys had brains with two operationally equal halves.

The Progress in Medicine Lectures are presented by the dean and faculty of Stanford Medical School, and by the Stanford Medical Center Council.

STANFORD—

Dr. Alf A. Lindberg, a Swedish scientist well-known for his research on bacteria of the *Salmonella* group, some of which cause typhoid fever and food poisoning, will present the Fifth Edwin W. Schultz Memorial Lecture on Thursday, May 3.

Entitled "*Salmonella* O Antigen: From Phage Receptor To Synthetic Vaccine," the lecture is scheduled for 4:15 p.m. in the Stanford Medical School Room M-104.

Health professionals in the area are invited to attend.

Lindberg has been an associate professor in bacteriology at the National Bacteriological Laboratory in Stockholm since 1971. His research may lead to a *Salmonella typhi* vaccine which is effective in preventing typhoid fever but does not cause a sore arm or other unpleasant side effects.

Common in areas with contaminated water supplies, typhoid fever raged throughout the United States in the 19th century. Leland Stanford Jr., in whose memory the University was founded, died in Italy in 1884 from this disease.

Typhoid has been virtually eliminated in the United States except for occasional outbreaks such as the 1973 epidemic in Florida in which 222 persons were infected.

In underdeveloped countries, however, several thousand cases are still reported yearly.

Salmonella bacteria also cause serious diseases in farm animals and are a common cause of food poisoning in humans.

Lindberg graduated from the Karolinska Institute Medical School in Stockholm in 1961 and presented his thesis on the structure of lipopolysaccharides in *Salmonella* in 1971.

He did postgraduate work from 1972 to 1974 in the Department of Medical Microbiology at Stanford and at the Walter Reed Army Institute of Research in Washington, D.C.

The Schultz Memorial lectures began in 1972, one year after the death of Edwin W. Schultz, a researcher in virology who taught at Stanford for 34 years.

The lectures are supported by a memorial fund established by his friends and family.

FOR IMMEDIATE RELEASE

STANFORD—

Jeanne D. Kennedy, director of resources development and special assistant to the president of the Institute of Medicine, Washington, D.C., has been appointed director of community relations at Stanford Hospital, effective Aug. 1.

Her appointment to the new position was announced by Peter Levin, executive director of the Hospital.

Kennedy will work closely with Hospital staff members in developing more personalized services. She also will interpret Hospital programs to area doctors, civic groups, and other interested citizens.

She will report primarily to Hospital Administrator Gary Mecklenburg.

Kennedy served as associate director of development for the Stanford Medical Center and as associate general secretary of the University during 1976-77.

Her present responsibilities at the Institute include fund-raising in the private sector, especially foundations and corporations; developing financial reports; and handling administrative responsibilities as assistant to the president, Dr. David Hamburg, on leave from the Stanford Department of Psychiatry.

During 1961-76 Kennedy compiled indexes to scholarly books. She also was a financial and accounting consultant for book publishing firms and community service organizations in the Peninsula area.

A 1954 graduate of Smith College, she worked with the Committee for Art at Stanford for several years before becoming its chairman in 1968-70. She initiated and directed planning for a docent program and museum bookshop, helping to raise more than $250,000 for the Art Department and Museum over a three-year period.

She is married to Donald Kennedy, a Stanford professor. They have two daughters, Page and Julia.

STANFORD—

Dr. Henry S. Kaplan of the Stanford University School of Medicine has been selected to receive the first Charles F. Kettering Prize for his research in Hodgkin's disease, the General Motors Cancer Research Foundation announced Thursday, April 12, in New York.

Kaplan, D'Ambrogio professor of radiology and director of Stanford's Cancer Biology Research Laboratory, was cited for his leadership in research that led to understanding of the biology of this type of cancer, and for the development of a treatment for Hodgkin's disease, the foundation said.

Kaplan was one of three researchers selected to receive the annual General Motors Cancer Research Prizes. Each of the prizes are named in honor of distinguished former GM executives.

The other recipients are Sir Richard Doll, regius professor of medicine, Master of Green College, Oxford University, England; and George Klein, professor of tumor biology at the Karolinska Institute, Stockholm, Sweden.

Dr. Doll will receive the Charles S. Mott Prize for his leadership in research concerning the environmental causes of cancer. Dr. Klein will receive the Alfred P. Sloan Jr. Prize for his pioneering studies on the inter-relation of cancer and the immune system in mammalian species, including human cancer.

The three researchers will receive their prizes, each consisting of a gold medal and a $100,000 tax-free award, at a presentation ceremony and dinner in Washington, D.C., May 2.

The award recipients were selected by the Awards Assembly of the GM Cancer Research Foundation established last September. It is composed of 25 internationallly prominent basic and clinical scientists and physicians.

"Each prize winner was chosen by the Awards Assembly after exhaustive analysis of their work by specialists in their separate fields," the foundation statement said.

More than 600 nominations, the foundation said, were received from 17 countries.

The awards to Drs. Kaplan, Doll, and Klein were announced by Dr. Joseph G. Fortner, president of the General Motors Cancer Research Foundation.

- more -

"This marks the beginning of a historic occasion in the field of cancer," Dr. Portner told a news conference this morning in New York.

"For the first time, individuals who have made hallmark contributions to our understanding of the cause, nature, treatment and prevention of cancer are being recognized in a manner commensurate with that afforded other scientific fields.

"The prizes are important to the individual, but they serve a second and equally important purpose in that they bring to the attention of the people of the world that highly significant progress is being made in an area which was once considered hopeless."

Hodgkin's disease, a cancer of the lymph glands, was invariably fatal and the best that could be done for patients was to make their remaining days comfortable.

"Although no single person is never wholly responsible for a particular scientific advance," the foundation statement said, "Dr. Kaplan is considered as the dominant figure in the reversal of this grim future for Hodgkin's patients.

"Today, Hodgkin's disease is one of the most curable of all cancers."

In the 1950's Kaplan conceived the use of the linear accelerator for medical purposes. After working with Stanford physicists to design the necessary apparatus, he set standards for its use.

As treatment advances were being made, Kaplan developed methods showing how other organs of the lymph system are involved in the cancerous process. He proposed diagnostic procedures, including special exploratory surgery, to meet these aims and allow the treatment of patients whose disease was more advanced.

Kaplan also demonstrated that the radiation activates a latent cancer-causing virus and that this was the genesis of leukemia in mice. "This was a major contribution," the foundation statement said, "showing that, at least in mice, some cancers are partly caused by viruses."

The General Motors Cancer Research Foundation was established in 1978 with an initial $2 million grant from the General Motors Corporation to fund the three annual awards.

The awards are named in honor of three men associated with General Motors. Mr. Kettering was inventor, manufacturer, researcher and former GM director, and pioneer in the establishment of GM laboratories. Mr. Mott was a longtime GM officer and director and renowned philanthropist; and Mr. Sloan, president and chairman of General Motors for 33 years, was responsible for establishing the Sloan-Kettering Institute for Cancer Research.

A leading critic of nuclear power and armaments will discuss the biological and political implications of the nuclear industry on Friday, April 20 at Stanford University School of Medicine.

Dr. Helen Caldicott, a pediatrician at Children's Hospital Medical Center in Boston will speak at 8 p.m. in Fairchild Auditorium, and will discuss medical issues relating to the recent nuclear accident at Three Mile Island.

She has been an active opponent of the nuclear industry both in the U.S. and in her native Australia, and has written a book entitled *Nuclear Madness* on these topics.

The lecture is open to the public as part of Environment month at Stanford, cosponsored by a student committee, the Associated Students Speakers Bureau, the Stanford Energy Information Office and the Stanford Workshops on Political and Social Issues (SWOPSI).

Stanford University Hospital's Pathology Laboratory has been accredited by the College of American Pathologists.

In a letter to Gary Mecklenburg, administrator of Stanford Hospital and Clinics, the national pathology organization said the accreditation runs through Dec. 13, 1980.

Dr. John K. Duckworth, chairman of the organization's commission on inspection and accreditation, said Stanford's most recent inspection "indicates a high level of medical laboratory performance."

In order to receive accreditation from the College of American Pathologists, institutions such as Stanford must participate in annual surveys conducted by the pathology organization.

STANFORD—

Stanford University Hospital has been certified as a participant in the California Voluntary Cost Containment Program.

Hospital administrator Gary Mecklenburg said that certification is a way of demonstrating that the hospital and its medical staff are committed, as part of an organized state and national effort, "to keep hospital costs as low as possible."

Certificates are granted those hospitals in California which endorse the goals of the Voluntary Program, and which agree to participate in the program's data collection activities.

Mecklenburg said that Stanford hospital has been attempting to hold down costs for the past two years.

In 1978, hospital costs increased 11.0 percent, down from an average yearly increase of 19.1 percent for the period 1973-77, he said.

And in the first six months of the current fiscal year, beginning September 1978, the rate of increase dropped to 8.5 percent.

Nationwide, $1.48 billion in hospital expenditures were saved during 1978, according to the National Steering Committee of the Voluntary Effort.

The figure is based on a reduction of the rate of increase in hospital costs, from 15.6 percent in 1977 to 12.8 percent last year.

The goal, proposed by the Carter administration, is a yearly cost increase of 9.7 percent by 1980.

In its resolution endorsing the Voluntary Program, the Stanford hospital board of directors stated that it "is strongly committed to voluntary action as the key to cost containment, and desires to play a leadership role in demonstrating the value of voluntary action in cost containment."

The resolution pledged "the use of all reasonable means to keep operating expenditures and capital budgets at the lowest reasonable levels on a continuing basis, consistent with sound medical practice in a teaching setting."

A three-session course on growth and development to be held at Stanford University School of Medicine beginning April 17 is now open for enrollment to adolescent boys between 12 and 14 years of age.

The course will be led by two pediatricians in the division of adolescent medicine, Dr. Jerry Klein and Dr. Paula Duke. Topics to be covered include height, weight and muscle changes, diets, nutrition, development of secondary sex characteristics, and acne.

"Many young teenagers have concerns about their physical development," says Dr. Duke, "and we are trying to devise ways to help them through this transition period."

A briefing session for parents will be held Monday, April 16 at 7:30 p.m. in room A335 at the Medical Center, and the boys' sessions will take place on two consecutive Tuesdays, April 17 and 24 from 4 to 5:30 p.m. in room C358. The last session will be scheduled at a later date.

The course is part of a research project being conducted by Dr. Duke. A similar course for adolescent girls was held in February.

For more information on enrollment, call Dr. Klein or Dr. Duke at 497-6891.

STANFORD—

Physicians at Stanford University Medical Center are testing the laser as a means of treating recurrent ear infections in children.

The new technique may make it possible to treat children without using general anesthesia and at half the cost, according to Dr. Richard Goode, associate professor of surgery at Stanford.

Goode reported on the technique April 3, at the national meeting of the Triologic Society in Los Angeles.

Recurrent ear infections are common among children and some adults who cannot clear their ears well. Fluid often accumulates in their middle ears, providing a perfect "swamp" for bacterial growth, and can impair hearing, said Goode.

Currently, most patients are treated by putting a hole in their eardrums, and inserting tubes to allow their ears to drain. The tubes can later be withdrawn, and the eardrums heal.

In adults, the procedure can be done under local anesthesia. But children are usually placed under general anesthesia, and the tubes inserted in the operating room.

"Children can't take being stuck with three to six needles in the ear to anesthetize it, especially those between three to five years old," said Goode.

"That's why most of them are put under general anesthesia."

The laser technique, on the other hand, involves numbing the eardrum without needles, and thus without the pain.

Goode places a solution of anesthesia into the ear canal, and drives it into the eardrum with an electric current. The procedure takes about 11 minutes, said Goode, and causes only a tingling sensation in the ears of some patients.

Next, Goode positions a carbon dioxide laser over the ear, marks a spot on the eardrum with a red light beam, and touches a foot pedal to activate the laser.

The laser produces a beam of bright light absorbed by tissue of all colors. At a relatively low power setting, 12 to 14 watts, it focusses light so intensely that its beam literally vaporizes the spot of eardrum tissue in a tenth of a second.

All the patients hear is a "pop" as the laser beam cuts a tiny hole one to two millimeters in diameter in their eardrum. They feel no pain. No tubes are inserted, as the hole stays open for about one month during healing.

So far, the laser technique has been applied successfully in laboratory animals, in several adult patients, and in two children, said Goode. He and his associates are now determining whether one month is long enough to drain the ears.

"The technique is still experimental," he said, "but preliminary success in adults encourages us to continue testing in children."

Goode estimated that the technique can be performed in the outpatient clinic for $200 to $300. Tube insertion in the operating room may cost $750.

Infection is a possible complication of the laser technique, said Goode, and of any procedure in which the eardrum is pierced. Patients therefore are cautioned not to get water in their ears until the eardrum heals over, and are given antibiotic eardrops.

So far, infection following laser surgery has occurred in only one patient, he said.

Another concern is that excess laser energy passing through the eardrum may damage the delicate structures of the middle and inner ear.

This is unlikely, said Goode, because the fluid which has collected in the ears of most patients completely absorbs excess energy.

"Ultimately, the laser technique may make it easier to treat at least half of patients with decreased hearing or recurrent ear infections due to fluid in the middle ear," he said.

STANFORD—

Seventy percent of medical students graduating from Stanford University School of Medicine this year have been matched to one of their top three choices for internship.

Fifty three percent of the 79 graduates seeking internships next year obtained their first choice, the highest percentage in the past 14 years, according to Dr. Kenneth L. Vosti, associate dean for student affairs.

The high match rate probably reflects a number of variables, said Vosti, including the students' clinical performance, and a counseling program which helps them apply for programs most appropriate to their abilities and career desires.

"For instance," he said, "some of our strongest students may not match with their first three choices, particularly if they choose to compete for positions at prestigious institutions to which hundreds of other highly qualified graduates apply."

To qualify for internship programs, medical students must first satisfy the graduation requirements of the Medical School, which include passing Parts I and II of the National Board Examinations, as well as the necessary course requirements of the Medical School, said Vosti.

Most of the graduates (33) will take graduate training in internal medicine. The remainder have been accepted, in descending order, by programs in pediatrics, surgery, family practice, psychiatry, pathology, anesthesia and dermatology.

This is typical, said Vosti. "Each year, nearly half of our students take internships in internal medicine or closely related fields."

In addition to the students' obvious interest in internal medicine, the discipline offers them greater flexibility than many others, he said, and provides an excellent foundation for further training in most other specialties.

Nevertheless, the internship programs chosen by students are good indicators of the general fields in which they eventually will practice, says Vosti.

This year's class has been accepted by programs from Los Angeles Children's Hospital to Johns Hopkins University in Baltimore.

The majority, 14 graduates, will be interning at Stanford, where they will make up over one fifth of the 65 internships offered this year.

STANFORD—

If King Tuthankamen were alive today, he probably would know what an enema is.

He would use honey as a dressing for his wounds, and he might believe that the poppy seed is useful for relieving intestinal gas.

But he would also be familiar with some aspects of current medical practice.

King "Tut" lived during the height of medicine in ancient Egypt, about 1350 B.C., according to Dr. Fernando G. Vescia, clinical assistant professor of medicine and medical historian at Stanford University School of Medicine.

Vescia, a gastroenterologist at the Palo Alto Medical Clinic, spoke on "Tuthankamen's Medicine" recently at the Medical School.

There are eight or nine known papyri which describe the practice of medicine 15 to 18 centuries before Christ.

"They record, for the first time in the history of the world, the beginnings of a rational medical system, based on the taking of a history, medical examination, diagnosis and treatment—much the same way it is practiced today," Vescia said.

There were two types of healers in ancient Egypt, he said, priests, who practiced magic, and physicians. But the line between them was only beginning to be drawn.

The priests were responsible for embalming and mummifying the remains of the pharaohs who had passed to the "other world."

They developed the surgical techniques for extracting the internal organs, including the brain, and preserving them separately.

However, surgery was not used to treat disease in living patients, Vescia said.

Instead, the physicians used a variety of herbal remedies to treat conditions ranging from open wounds to hemorrhoids.

For example, a preparation of acacia leaves was prescribed for disorders of the anus, and as a contraceptive.

Today, physicians know that acacia leaves produce lactic acid. Similarly, demulcents, or oily substances, are used in current hemorrhoidal ointments, and contraceptive foams work because of their acidifying action, Vescia said.

- more -

The Egyptians also applied a mixture of one part honey and two parts grease as a salve for wounds.

Honey contains small amounts of gluconolactone, a mild antibiotic, and hydrogen peroxide, a sterilizing agent, introduced during honey production by bees, he said. Recent studies have shown that mixtures of honey and butter can completely sterilize cultures of bacteria such as *E. coli* and *Staphylococci.*

The poppy seed has been used since antiquity for the pain relieving and hallucinogenic properties of the opium obtained from it.

However, the Egyptians used it to prevent intestinal gas. "Today, we use codeine, an opiate derivative, to relieve not only intestinal cramping, but pain elsewhere in the body," Vescia said.

The central idea in medicine at the time of the pharaohs was that disease originated from unclean residues in the body, such as "ukedu" (stools), phlegm, bile, and even sperm.

"Ukedu was the main concern of the Egyptians," he said, "hense the popularity of the water enema." By removing the unclean part of the body, they believed that they could prevent disease.

This belief was passed on to the Greeks, and persisted into the 20th Century, when blood-letting was still used to treat a variety of illnesses, Vescia said.

Another practice, that of wearing precious metals to ward off evil and disease, is evident today, he said, in the popular belief that wearing copper bracelets will reduce the symptoms of arthritis.

However, some ornamentation, such as the green eye liner used by the Egyptians, actually had medicinal value. The make-up was produced from copper sulphates, which have sterilizing qualities, dissolved in alcohol.

The preparation was later modified by the Arabs to a black eye make-up commonly known as mascara in the West.

In some ways, "the magic of King Tut is as evident today in general society as it was then at court," Vescia said.

STANFORD—

Mother alone is not the ideal caretaker for young children, says a Stanford University professor who has been studying early child care over the past 10 years.

Although in our society, it's considered "ideal" for a child's development when a mother cares exclusively for her child, the brothers, sisters and friends who share in caretaking significantly enhance a child's intellectual and emotional development, says Dr. Herbert Leiderman, professor of psychiatry and behavioral sciences.

Based on studies conducted in a Kikuyu community outside Nairobi, Kenya, Leiderman found that, particularly in lower economic groups, multiple caretaking affected childrens' learning abilities.

Among the Kikuyu, young girls and occasionally young boys take over a substantial portion of the daily care of infants as young as five months old while the mother labors away from home.

Leiderman compared cognitive and emotional test scores of infants raised primarily by a mother and infants who received as much as 75 percent of their daily care from siblings or older peers.

In families from the village's lower economic group, Leiderman observed that infants cared for by a mother alone produced the lowest scores while the presence of alternate caretakers significantly improved an infant's test performance.

Older peers or siblings may provide unique forms of social stimulation not given by an adult which contribute to the enhanced learning observed.

In addition to contrast from the primary caretaker's attitudes, stimulating play, often lacking in the adult/infant relationship is a distinctive feature of such associations, Leiderman says.

A more intuitive understanding of the gaps in a young child's experience as well as less formidable stature and less forbidding approach may also contribute to the enhanced learning effect achieved by the infants' caretakers, the study suggests.

Few societies apart from those of the United States and western Europe depend so heavily on a single figure for rearing children early in life, says Leiderman. "The importance of a single, stable figure for optimizing subsequent growth has always been assumed in western society," he notes.

Cautious about applying these results directly to child-rearing in the United States, Leiderman suggests that the mother/child relationship as the only accepted standard deserves further scrutiny.

Denying that his findings necessarily promote large families with many children, Leiderman suggests that very young children and infants could benefit from interactions with older peers other than their siblings.

Strict grade stratification prevalent in American schools may not be ideal for childrens' development, he adds.

Leiderman described his research at a recent seminar on child psychiatry sponsored by the Friends of Psychiatry and Behavioral Sciences and held at the Children's Hospital at Stanford.

He is continuing his studies of multiple caretaking in more varied communities in Kenya and in the United States.

STANFORD—

You can defeat arthritis.

So says Dr. James F. Fries to patients in his new book, *Arthritis—A Comprehensive Guide*, (Addison-Wesley, Mass., $6.95).

Fries, associate professor of medicine at Stanford University School of Medicine, says the idea that "nothing can be done for arthritis" is not true.

On the contrary, "the battle against certain forms of arthritis is nearly won," he says.

No longer need patients with rheumatoid arthritis, for example, accept the pain, crippling and grotesque deformities once associated with the disease.

"Both arthritis and deformity can be prevented by sound use of present medicines and surgery together with your hard work," he says.

Fries, who has co-authored two other self-help books entitled *Taking Care of Yourself* and *Taking Care of Your Child*, says that treatment of arthritis, like other illnesses, begins in the home.

"Your knowledge is critical to your health," he says. "Your doctor will be a great help to you. But you have to make the decisions and carry them out."

In the first part of the book, Fries describes several of the over 100 forms of arthritis, and helps patients determine which form they have and what the best treatments are for it.

In every case, he advises patients to seek help early.

"Even the worst form of rheumatoid arthritis tends to get better with time. However, deformities don't improve. Therefore, it is extremely important to treat the disease correctly in the early years," says Fries.

In the second part of the book, Fries details ways of managing and preventing arthritis.

"Presently available drugs (such as aspirin and the anti-inflammatory agents) are truly excellent when used in combination with a sound overall program," he says.

But patients must understand that every drug has side effects, and that some, like aspirin, must be taken for weeks before they begin to control inflammation. Often, doctors must try a variety of medications before they find the best agent. "The treatment for your arthritis will ultimately be unique to you," says Fries.

Steer clear of pain relievers, like Tylenol, he says. They only deaden the pain without controlling the inflammatory processes which can lead to joint destruction.

In addition to taking medication, exercise, advises Fries. Activities, such as walking and swimming, build strength in the bones and ligaments surrounding arthritic joints, and help preserve their flexibility. Activity also is the way cartilage, which has no blood supply, obtains food and oxygen. Without it, the cartilage will begin to deteriorate.

"There is no special diet for arthritis," says Fries. "There are many kinds of arthritis, and there cannot be a single cause or cure for all kinds.

"It is tempting to accept a simple answer to a complicated problem, but it just isn't that easy."

The search for a simple answer has led over half of arthritis patients to try quack remedies, such as flu shots, or wearing copper bracelets.

The attitude of many patients is, "What's the harm? What do I have to lose?"

Plenty, says Fries. Several hundred million dollars each year are spent on quack treatments, and that doesn't account for the loss of confidence, dignity, function, and occasionally life itself when useless and sometimes dangerous remedies are tried.

Proper management of arthritis also includes taking care of the financial side, says Fries. He provides tips on buying generic rather than the more expensive brand name drugs, and on avoiding unnecessary lab and X-ray tests, and hospital stays.

In the third part of the book, Fries discusses how patients can cope with everyday problems, such as pain, medication side effects, getting around, sex, and work.

Decision charts are included to help patients decide whether to treat these problems at home or to see a health professional.

Some patients with arthritis suffer depression. "Perhaps this is because many of us associate arthritis with long-term pain, encroaching old age, or inevitability and hopelessness," says Fries.

However, all patients can lead satisfying lives.

"If your arthritis is serious," he says, "it may represent the greatest challenge of your life. Meeting that challenge may be your greatest satisfaction. You need a bit more will and determination and self-discipline than others. But the future is still yours."

STANFORD—

Basic research on the causes of alcoholism should receive more support, according to a Stanford University professor of pharmacology.

Dr. Dora Goldstein, commenting on her recent election as president of the Research Society on Alcoholism, explained that "the recent emphasis on treatment of alcoholism has done a lot of good, but at the same time, it may have persuaded people that the causes of alcoholism are well understood."

This is not so, she added, and as president of the Research Society on Alcoholism, Goldstein will seek support for basic research with the long range goal of determining the biochemical basis of alcholism and finding a medical treatment for the condition.

Goldstein said that although Health, Education and Welfare Secretary Califano has put alcohol just behind tobacco as a national health problem, research support on alcoholism still hasn't been boosted.

Biochemistry, neurochemistry, liver disease and genetics are some of the promising areas in which alcoholism research is active, said Goldstein, and her own research during the past eight years has focused on the molecular basis of alcohol addiction.

Goldstein and her associate, Dr. Jane Chin, have evidence that alcohol affects the lipid, or fat, component of nerve cell membranes, increasing membrane fluidity.

The lipid layers hold vital proteins in the membrane and the precise degree of fluidity is crucial for the proteins' proper function.

Goldstein and her colleagues have observed mice which have developed tolerance to high levels of alcohol. Membranes from these mice are subtly altered in structure and contain notable increases in cholesterol levels.

Furthermore, these "tolerant" membranes do not increase in fluidity as do the normal membranes when more alcohol is applied.

Since humans also develop tolerance to alcohol after prolonged use, further investigation of this altered membrane structure is necessary, according to Goldstein.

If membrane lipids and cholesterol are the key to alcohol's long-term effects, then "we may be able to manipulate alcoholism by dietary means" as in heart disease, Goldstein suggested.

The Research Society on Alcoholism, a component group of the National Council on Alcoholism, is composed of about 300 active researchers. The goal of the organization is to increase support for alcohol research and to enhance communication among alcoholism researchers, said Goldstein. The group holds regular conferences and publishes a quarterly journal entitled *Alcoholism: Clinical and Experimental Research*.

Dr. John W. Farquhar, professor of medicine at Stanford University School of Medicine, has been appointed to the Advisory Committee for the Division of Health Promotion and Disease Prevention of the Institute of Medicine, (National Academy of Sciences) in Washington, D.C..

Acknowledging a new importance in "the promotion and protection of health," the division will devote attention to such issues as the effectiveness of prevention methods, techniques for educating the public on health matters, and legal and ethical issues in health protection policy formulation.

Farquhar received his M.D. degree from the University of California School of Medicine and has been at Stanford since 1962. He is director of the Stanford Heart Disease Prevention Program, and is actively involved in studies on the causes and prevention of cardiovascular disease.

A resident physician in neurology at Stanford University Medical School is the recipient of the S. Weir Mitchell Award by the American Academy of Neurology.

Dr. Lawrence Steinman received the award and a $500 honorarium April 27 at the academy meeting in Chicago for research into the causes of nervous system diseases such as multiple sclerosis.

The award, named after a famous American neurologist, is given annually for excellence in research by resident physicians.

Steinman's work was conducted at the Weizman Institute near Tel Aviv, Israel from 1975 to 1978. The work was supported in part by the National Institutes of Health.

Multiple sclerosis is a progressive disease characterized by muscle weakness, incoordination, and other symptoms.

It is related to a loss of myelin, the protective sheath which covers nerves. Scientists believe it may be due to an attack by the body's immune system which destroys the myelin.

However, the cause of the disease is not well understood, and there is no cure.

Steinman studied the influence of myelin protein on the development of experimental de-myelinating disease in animals.

Previous investigators had shown that a soluble form of myelin protein (one which dissolves in water), prevents the disease in animals.

In addition, Dr. Jonas Salk, of the Salk Institute in San Diego, has been testing myelin protein in patients with multiple sclerosis.

The rationale for using myelin protein is that it may supply a target for the immune responses, redirecting them away from the nerves, said Steinman.

Steinman, now in his second year at Stanford, is continuing his studies in animals. He said his goal is to understand better what causes diseases such as multiple sclerosis and how they may be controlled.

The third and final in a series of public lectures by Stanford neuroscientists on the human brain will be presented Wednesday, May 16, at Stanford University School of Medicine.

Dr. James H. Dewson III, will discuss similarities researchers have found in the left-right organization of the human brain and in the brain of monkeys. His talk, "How Do Monkeys Use Their Heads?" will also highlight studies of how primates remember what they've heard.

The address begins at 7:30 p.m. in Fairchild Auditorium at the medical school.

Previous talks in the Spring Progress in Medicine Lecture Series have been by Drs. John G. Nicholls and David A. Prince.

Dewson is associate professor of speech and hearing sciences in the Department of Surgery, and acting director of the Division of Laboratory Animal Medicine.

His research with monkeys led to the discovery in 1976 that these primates possess a type of brain which had earlier been asociated with man's specific intellectual capacities. Prior to that researchers had generally determined that monkeys had brains with two operationally equal halves.

A graduate of the University of Arizona, Dewson received his Ph.D. from Stanford in 1961. His professional career has been at Stanford since he began as a postdoctoral fellow in the Department of Psychiatry in 1961.

The Progress in Medicine Lectures are presented by the dean and faculty of Stanford Medical School, and by the Stanford Medical Center Council.

"Being Human," an hour-long special documentary produced by the Office of Postgraduate Education at Stanford University School of Medicine, will be broadcast in the San Francisco Bay Area May 26-27.

The program, which focuses on the unique characteristics that set the human species apart from other creatures, will be telecast by KQED-TV, Channel 9, at 9:30 p.m. on Saturday, May 26, and at 10:30 p.m. on Channel 32 (UHF) on Sunday, May 27.

The views of 16 accomplished artists and scientists are featured on the documentary, which is narrated by Eric Sevareid.

Dr. Edward Rubenstein, professor of clinical medicine and associate dean of postgraduate medical education, wrote and produced the program, which is the first to be produced for the general public by the Office of Postgraduate Medical Education. It was originally telecast nationwide by the Public Broadcasting Service (PBS) on May 6, but it was not carried by KQED.

Participants in the production are Judith Blegen and Frederica von Stade of the Metropolitan Opera; Norman Cousins, author and editor of *Saturday Review;* Dr. David Hamburg, president of the Institute of Medicine of the National Academy of Sciences (and currently on leave of absence from the Stanford faculty); Dr. Robert Hofstadter, physicist and Nobel laureate at Stanford; and vocalist Ella Fitzgerald.

Also, Dr. Rene Dubos, biologist at Rockefeller University; Dr. Philip Handler,president of the National Academy of Sciences; concert violinist Yehudi Menuhin; Dr. Joshua Lederberg, Nobel laureate and president of Rockefeller University; sculptor Henry Moore; Dr. John Nicholls, neurobiologist at Stanford; Dr. Linus Pauling, Nobel laureate and director of the Linus Pauling Institute for Science and Medicine; Ava Helen Pauling; concert pianist Arthur Rubinstein and Mrs. Arthur Rubinstein.

STANFORD—

A device developed by Stanford University scientists for detecting hearing loss in newborn infants has shown that seriously ill babies are 19 times more likely to be deaf than healthy ones.

The device, called a crib-o-gram, has been tested in 12,000 infants at Stanford University Hospital since 1970. So far, it has detected deafness in 11 healthy babies of a total of 10,400, an incidence of one per 1,000.

However, 31 out of 1,600 seriously ill babies in the intensive care nursery were found to be deaf, or one in 52.

"This is the first study which has shown a high incidence of deafness among babies in an intensive care nursery," said Dr. F. Blair Simmons, head of the Medical School's division of otolaryngology.

Simmons reported the findings April 3 at the meeting of the American Triological Society in Los Angeles.

The research was supported in part by grants from the National Institute of Neurological Diseases and Stroke.

The crib-o-gram, developed by Simmons and Frederica Jones, R.N., monitors infant movements before, during and after a test sound is emitted from a microphone.

Slight changes in movement, even breathing and heart beats, are detected by a transducer located near the infant, and relayed to a microprocessor.

The microprocessor grades the infant's response to 30 test sounds given over a three to six hour period. If the infant responds in a statistically significant way, a green light goes on, indicating that he or she has passed.

If the infant fails to respond reliably, a red light goes on, indicating failure. An amber light means that testing is in progress.

Infants who fail the test are called back to the clinic at seven months of age for further screening. Those who again fail are referred to an audiologist.

Simmons analyzed the medical records of the ill babies who were deaf, and found that 74 percent of them had histories of fetal distress during labor or delivery, or had suffered severe apnea episodes, periods during which they stopped breathing, during the first week of life.

-more-

"It would thus appear that anoxia, lack of oxygen, or the results of it, is the underlying factor in a majority of neonatal deafness," said Simmons.

"This is the first clue we've had to the real causes for deafness other than genetics."

Simmons said some babies appeared to become progressively deaf after they left the hospital, and that the crib-o-gram failed to detect hearing losses later discovered in two infants.

However, he said, one of the infants appeared to have rubella at birth (a condition known to cause deafness), and the other had a history of respiratory distress during its first weeks of life.

In addition, Simmons found the average incidence of deafness in ill and healthy babies combined was about 3.5 per thousand, similar to national estimates of the incidence of deafness among six-year-olds.

"I think genetic delayed-onset hearing losses are quite rare during the first 18 months," he said. "We have yet to encounter one."

Simmons said this finding gave increased importance to newborn hearing tests.

Hearing rehabilitation is most successful if it is begun around six months of age, he said. However, severe hearing problems in most children currently are not picked up until they are over two years old.

"There is solid data showing that even lesser degrees of hearing loss can have a tremendous impact on language and learning behavior," he said.

The crib-o-gram is an efficient and inexpensive method of performing newborn hearing tests, said Simmons.

The device costs $4,700, and requires very little training or time to operate. Costs to the hospital would amount to about $5 per test, he said.

In comparison, brain stem audiometry equipment, which measures changes in brain waves in response to test sounds, may cost a hospital $15,000, and requires a skilled technician to run it. Each test per patient may cost between $70 to $90, said Simmons.

The crib-o-gram is being manufactured by Telesensory System, Inc., under a patent agreement with Stanford University. The device is available to intensive care nurseries throughout the country.

The Palo Alto firm, which also produces the Optacon reading aid for the blind, helped design early prototype models of the crib-o-gram, and designed and developed the microprocessor model.

Simmons said the crib-o-gram has also been tested in about 6,000 infants in 14 hospitals throughout the U.S. and in Nova Scotia. The results of the study, which began in 1976, will be made available within a year, he said.

STANFORD—

The discoverer of nerve growth factor, a protein that regulates development of nerve cells, will present the sixth annual Katharine D. McCormick Distinguished Lecture on Monday, May 21 at 5 p.m. in Fairchild Auditorium at Stanford University School of Medicine.

Dr. Rita Levi-Montalcini, director of the Cell Biology Laboratory, Consiglio Nazionale delle Ricerche in Rome, will discuss "Recent developments in the study of nerve growth factor."

A graduate of the University of Turin in 1936, Levi-Montalcini observed in 1951 that some tumors produced a substance that caused rapid growth of nerve cells.

Since her initial discovery, a large field of research on nerve growth factor has developed to which Levi-Montalcini continues to make important contributions.

She is the recipient of numerous awards for outstanding scientific achievement and is a member of the National Academy of Sciences.

The McCormick Distinguished Lectureship was established in 1974 for the purpose of bringing outstanding women physicians and scientists to lecture at Stanford Medical School.

The lectures honor the late Katharine Dexter McCormick, who left a large bequest to the medical school, particularly "for the encouragement and assistance of women in pursuing the study of medicine, in teaching medicine, and in engaging in medical research."

The lecture is open to the medical community and to the public.

Dr. Irvin D. Yalom, professor of psychiatry and behavioral sciences at Stanford University School of Medicine, has been awarded a Foundations' Fund Prize for Research in Psychiatry from the American Psychiatric Association.

A prominent researcher in the field of group psychotherapy, Yalom was specifically cited for his books on research in psychiatry.

These include *The Theory and Practice of Group Psychotherapy* (Basic Books, New York, 1975), considered a classic text in the field; *Encounter Groups: First Facts* (Basic Books, 1972); and *Every Day Gets a Little Closer* (Basic Books, 1974), an examination of the patient-psychiatrist relationship written with a former patient with the pen name of Ginny Elkins.

In addition to his work in group psychotherapy, Yalom is known for his studies on the relationship of hormones to behavior and the counseling of dying patients.

In 1974, Yalom received the Edward Strecker Award from the Institute of Pennsylvania Hospital for outstanding contributions to the field of psychiatric care and treatment.

A graduate of Boston University Medical School, Yalom has been at Stanford since 1963.

Yalom and two other award winners were presented with $500 awards and commemorative plaques at the Convocation of Fellows during the annual meeting of the American Psychiatric Association in Chicago on May 14.

Night terrors, some forms of bed-wetting, and sleep walking in children may be due to an immaturity in the neurologic mechanisms involved in sleep, according to Dr. Thomas Anders, associate professor of psychiatry and pediatrics at Stanford University School of Medicine.

"These problems are probably due to a defect in sleep, and are not related to family or emotional problems, as previously thought," he said.

Anders discussed research on the sleep of children Thursday, May 10, at a seminar on child psychiatry at Children's Hospital at Stanford.

The seminar was sponsored by the Friends of Psychiatry and Behavioral Sciences, a community group which supports the department.

Night terrors are common in children between the ages of two and five, said Anders.

Usually, the child wakes up, screaming inconsolably. His heart is beating rapidly. He is perspiring, and is clearly in distress.

But, said Anders, the child is not awake. After one or two minutes, the child falls back into quiet sleep, and cannot remember the episode in the morning.

Night terrors can be clearly distinguished from nightmares, he said, which usually wake children up and which can be recalled.

Sleep walking is a related problem which occurs in 15 percent of all children, usually between the ages of five and 11. Frequently, the child who had night terrors also walks in his sleep, said Anders.

These children may walk for as long as 30 minutes, during which they cannot be aroused. Eventually, they go back to bed, and have no memory of the episode.

"Sleep walking is purposeless," said Anders. "Persons who walk in their sleep are not acting out their dreams. Their motions are repetitive and poorly coordinated."

But sleep walking can also be very dangerous, he said. The first treatment for sleep walking is "child-proofing" the house for safety, to prevent children from falling down stairs or out of open windows.

Like night terrors and sleep walking, talking during sleep and some forms of bed-wetting also occur in some children during the shift from quiet to active sleep.

All of these problems share several common characteristics, including family history of sleep disorders, and a higher incidence among males. According to studies by Dr. William C. Dement and his associates at the Stanford Sleep Research Center, there is also evidence of neurologic immaturity, said Anders.

-more-

Another sleep problem studied at Stanford is sudden infant death syndrome (SIDS), also called crib death, in which previously healthy babies die suddenly during the night.

"SIDS is the leading cause of death among infants between one week and one year of age," said Anders. Three to six infants per 1000 die of SIDS each year.

Anders said SIDS may be related to a type of sleep apnea, a condition in which adults as well as infants stop breathing at times during sleep.

There seems to be an obstruction in the air canal of these people, preventing the flow of air even though the diaphragm is contracting. However, no obstruction can be found when patients are examined while they are awake.

Repeated episodes of apnea drastically reduce the level of oxygen in the blood, and can lead to abnormal heart rhythms and death, he said.

Dement and Dr. Christian Guilleminault have identified a population of "near miss" infants who had stopped breathing, but who were revived by their parents. These infants seem to outgrow the sleep apnea by their first birthday, said Anders.

"The first year is the critical period," he said.

Anders has also been studying normal sleep in infants.

With the help of an infrared video camera and time lapse photography, Anders and his colleagues recently studied 40 infants while they slept in their own homes.

"This is the first study which looks at the data of what happens in the night at home," said Anders.

The researchers found that two-week-old infants spent 50 percent of the time in active sleep, confirming earlier laboratory studies which had measured rapid eye movements (REM) and brain waves.

In addition, half of babies in the study between two weeks and nine months old awoke during the night, while the other half slept through the entire recording period.

Daytime sleepiness in adolescents is being studied at the Stanford Summer Sleep Camp, directed by Dement and research assistant Mary Carskadon.

Some studies have indicated that teenagers suffer from chronic sleep deprivation. In fact, Anders, Carskadon and Dement have shown that by the age of 13, most children sleep an hour more during the weekend than they do during week nights.

However, daytime sleepiness still occurred among residents of the sleep camp despite the fact they were asleep 10 hours each night. This suggests that hormonal changes accompanying puberty may also play a role in the sleepiness of adolescents, he said.

STANFORD—

Despite the high incidence of epilepsy in the United States, not enough money is being spent on research related to its causes and treatments, a Stanford University physician told a full house in Fairchild Auditorium on campus Wednesday night.

"Epilepsy is one of the most common maladies a neurologist treats, affecting between two and four million Americans," said Dr. David Prince, professor and chairman of the department of neurology.

"As recently as 1975, when over $3 billion were spent on the whole problem of epilepsy, less than one percent of this amount was devoted to research," he added.

Although there are many effective drugs available to treat the disease and many epileptics lead normal, productive lives, about 20-25 percent of all epileptics still cannot be adequately treated with the available methods, he said.

"These people are waiting for us to develop more knowledge about epilepsy," he said, and find more effective agents to control the condition.

Prince explained that although epilepsy is typified by rapid uncontrolled firing of nerve cells in the brain, we still don't understand what causes the phenomenon.

During an epileptic seizure, abnormal waves are seen on an electroencephalogram (EEG), a standard test in which electrical signals representing the activities of many nerve cells in the brain are recorded from electrodes glued on the scalp.

Future research on how the brain functions and regulates itself may hold promise for better understanding of epilepsy, said Prince, and a number of new approaches are being applied in this area.

Prince explained that the brain itself produces substances which have been shown to cause epilepsy in animals. Minute quantities of endorphins, the body's natural anti-pain substances, injected into brain tissue cause EEG changes characteristic of epilepsy, he said.

"Perhaps the problem in some kinds of epilepsy is that the brain has lost its ability to regulate how much of these or other regulatory substances are made," he suggested.

Prince added that future research also will focus on finding natural or synthetic compounds which can limit the uncontrolled cell firing.

Prince concluded by noting that at least one form of epilepsy is preventable. "The incidence of post-injury epilepsy has fallen considerably since the lowering of the speed limit," and the widespread use of seatbelts in automobiles, he said.

Prince's talk was the second in the spring Progress in Medicine lecture series on the brain, presented by the dean and faculty of Stanford Medical School and by the Stanford Medical Center Council.

The last lecture in the series will be held Wednesday, May 16 at 7:30 p.m. in Fairchild Auditorium when Dr. James H. Dewson will discuss "How do monkeys use their heads?"

STANFORD—

Stanford University scientists have found new evidence that an eye disorder which can cause protruding eyeballs, double vision, and loss of sight results from an attack of the body's immune system on eye muscles.

Their work demonstrates the feasibility of an immune attack by lymphocytes, a type of white blood cell, on an artificial membrane outside the body.

The technique employed in their work has fundamental importance, because it may help scientists understand the mechanisms involved in cell-mediated immunity, as well as so-called auto-immune diseases and cancer, said Dr. Joseph Kriss, head of the division of nuclear medicine at Stanford University School of Medicine.

The eye disorder, called Graves ophthalmopathy, is characterized by an infiltration of white blood cells into the muscles of the eye, causing massive swelling, poor muscle function, and forward protrusion of the eyeball.

It can lead to substantial loss of sight.

Usually, the disease is accompanied by excess production of a protein, thyroglobulin (Tg), by the thyroid gland, and also by production of antibodies, immune system molecules which combine with the protein.

The thyroid protein has been found on the membranes of eye muscle cells, but not on skeletal muscle elsewhere in the body.

Scientists believe that complexes of thyroid protein and its antibody form on the surface of eye muscle cells, stimulating attack by white blood cells on the eye muscle.

However, researchers have been unable to confirm this theory, because of the inaccessibility of human eye muscles, which lie deep within the orbit behind the eyeball.

For this reason, Kriss and research associate Dr. S. Qasim Mehdi constructed artificial membrane vesicles, tiny spheres made of phospholipid molecules and eye muscle membrane protein, and containing a radioactive marker.

- more -

The spheres were incubated in a solution of white blood cells from patients with the disease, and thyroid protein or the protein-antibody complex.

The attack of white blood cells was measured by the extent of release of radioactivity from ruptured or damaged spheres.

Kriss and Mehdi found that eye muscle protein was a necessary ingredient of the sphere membrane for attack by white blood cells. Even in the presence of thyroid protein, spheres made without eye muscle protein were not ruptured.

Thus, the researchers found that an attack by white blood cells is probably responsible for the swelling and damage observed in Graves ophthalmopathy, and that both thyroid protein and a factor in the eye muscle membrane are required for the attack to occcur.

Their work was reported in the April issue of the *Proceedings of the National Academy of Sciences.* It is supported by a grant from the National Institute of Arthritis, Metabolism, and Digestive Diseases.

"It may be that a component of eye muscle membrane, as yet unidentified, provides a means of attaching the thyroid protein, which then activates the attack by white blood cells," said Kriss.

Kriss said the work was important because it provided the rationale for a current treatment of the eye disease, orbital supervoltage radiation therapy.

The treatment was pioneered at Stanford 10 years ago by Kriss, Dr. Sarah Donaldson, associate professor of radiology, and Dr. Malcolm Bagshaw, chairman of the department.

It employs a fine beam of X rays aimed at the eye muscles in order to kill off the attacking white blood cells without damaging delicate adjacent structures.

So far, about 200 patients have been treated at Stanford, with a marked improvement in 65 to 70 percent of the cases.

The work by Kriss and Mehdi also opens the possibility of using membrane vesicles to study immune reactions under a variety of clinical conditions.

For instance, said Kriss, workers in his laboratory, Drs. Nurit Hollander and Irving Weissman of the department of pathology, and Dr. Harden McConnell, professor of chemistry, are using the spheres to study factors influencing cellular immune attacks against viral-induced cancer in mice.

"Eventually, we hope to be able to test to what extent patients with cancer develop cell-mediated immunity against their own tumors," he said.

STANFORD—

Bedwetting among adolescents is frequently a sign of other serious problems which can affect a teenager's self-image and social life, according to a study by researchers at Stanford University School of Medicine.

Dr. Ruth T. Gross, McCormick professor of pediatrics, presented recent data on the multi-handicapping condition of enuresis at last week's joint national conference of the American Pediatric Society and the Society for Pediatric Research in Atlanta, GA.

"Both parents and pediatricians have taken the attitude that enuresis is something the adolescent will outgrow," Gross said. "But the true impact of enuresis has not been appreciated. It goes beyond the nuisance and embarrassment of wet sheets. The symptom may be an indication of other seriously handicapping problems."

Data collected from a National Health Examination Survey which sampled almost 15,000 children and teenagers in the United States, revealed that bedwetting is more frequently found in males, in blacks and in lower socioeconomic groups.

Interviews with school personnel also revealed that these teenagers were perceived to be more often the lower one-third of their class in academic ability and achievement, had higher rates of absenteeism, were less popular with their peers and often needed more discipline than non-enuretics.

Of the 3600 males and 3500 females aged 6 to 11 sampled in the survey, 22.9 percent of the boys and 12.2 percent of the girls reported wetting their beds. The incidence decreased among similar numbers of adolescents sampled, with 5.5 percent of the males aged 12 to 17 and 3.1 percent of the females reporting enuresis.

"Our data reinforce an earlier British study which found correlations between enuresis, sex and age," Gross said. "However, enuresis seems to be more common in the United States than in most countries, and we don't know why."

There is also no confirmed explanation for the increased frequency among males than among females, though Gross suggested one explanation.

- more -

"I tend to believe enuresis is one part of broader developmental delay," she said. "There is an association between enuresis and late physical and sexual maturation, and this may relate to the higher frequency among males, who more commonly have developmental delays."

The study also revealed that parents tend to have negative feelings toward their enuretic children. Parents demonstrated lower educational expectations, and they considered the adolescents to be nervous.

"We were particularly struck by the finding that a much higher percentage of parents of non-enuretic than of enuretic males expected their children to attend college, and the difference increased with the age of the children," Gross said.

This difference was even more striking in parents of female enuretic and non-enuretic children, she added.

The negative attitudes seemed to be gradually passed on to the teenagers. However, these lower expectations were not expressed by the children until age 14 in females and 15 in males.

"Indeed, at earlier ages, they are likely or more likely to expect to attend college," Gross said.

Other problems such as difficulty walking, insomnia, bad dreams and tenseness were also reported more often by enuretics than by non-enuretic children and teenagers.

"In light of these findings, pediatricians and parents must make sure that there is an investigation into the children's other difficulties," Gross said. "Bedwetting must not be seen as an isolated or unimportant symptom. It is a potential component of a multi-handicapping condition."

Other Stanford researchers who worked on this project were Dr. Paula M. Duke, Robert Wood Johnson clinical scholar; John A. Martin, postdoctoral fellow in psychology; J. Merril Carlsmith, professor of psychology and Sanford M.. Dornbusch, professor of sociology.

The study was partially supported by the Boys Town Center for the Study of Youth Development at Stanford and the Robert Wood Johnson Foundation.

STANFORD—

Heating by ultrasound is being tested as a treatment for psoriasis by Stanford University researchers.

In a preliminary study of 21 psoriatic lesions, localized heating by ultrasound (hyperthermia) resulted in complete clearing of 13 lesions, or 62 percent.

"We are not suggesting that hyperthermia is a new treatment for psoriasis at present," cautioned Dr. Elaine K. Orenberg, senior research associate in the department of dermatology, Stanford University School of Medicine.

Additional studies are needed to determine the potential application of the technique. However, "hyperthermia may help us better understand the mechanisms associated with the psoriatic disease process," she said.

Orenberg conducted the research with Dr. David G. Deneau, assistant professor of dermatology, and Dr. Eugene M. Farber, professor and chairman of the department.

She reported the findings May 9 at the national meeting of the Society of Investigative Dermatology in Washington, D.C.

In an interview, Farber said this was the first study of controlled hyperthermia in psoriasis, a common skin disorder which produces itching, scaling, and redness.

He said he had observed that patients with psoriasis improve in the summer, whether they are exposed to sunlight or not. This suggested that heat may have a role in the improvement.

In the study, lesions up to four centimeters in diameter were chosen for hyperthermia treatments. None of the patients had received other drugs or ointments for one to three months prior to hyperthermia, and no medications were used on the lesions during the study.

The lesions were heated to between 43 and 44.5 degrees centigrade for 30 minutes, for a total of six to 10 treatments using an ultrasound transducer operating at a frequency of five megahertz.

"This form of therapy is non-toxic, and non-invasive, and none of the patients in the study suffered burns as a result," said Orenberg.

At the end of the study, 13 of the treated lesions, or 62 percent, had cleared completely. Six lesions had a partial response to hyperthermia, and the lesions in two patients were unchanged. These two lesions also were unresponsive to other psoriasis treatments.

The response seems to be temporary, said Orenberg. Some of the lesions remained clear for two to three months.

Farber said it was too early to compare hyperthermia with other treatments for psoriasis. Although most of the lesions improved substantially, response was limited to the two centimeter square area exactly under the ultrasound transducer.

"This may mean that hyperthermia would be more useful in treating localized plaques than extensive lesions covering large areas of the body," he said.

STANFORD—

Ronald D. Twomey has resigned as director of personnel at Stanford University Medical Center to become director of human resources at Parkview Memorial Hospital in Ft. Wayne, Ind.

Twomey, 44, will depart Stanford June 15.

Since 1976 he has directed a combined personnel section for Stanford Medical Center, serving Stanford Hospital and Clinics, and Stanford Medical School.

He previously worked for the Arthur Young Co. of Chicago, a consulting firm, and the University of Chicago Hospitals and Clinics as associate administrator.

STANFORD—

Men whose mothers took DES, a synthetic form of estrogen, during their pregnancy, are being sought by Stanford University Medical School researcher Dr. Robert Kessler.

Kessler, assistant professor of surgery, is attempting to confirm a suspected link between DES and reproductive system abnormalities, including sterility and genital tumors.

If the link is confirmed, he and his associates in the division of urology will study ways of reversing the damage, he said.

In a preliminary study of 50 DES-exposed males, Kessler said he found no increase in abnormalities compared with non-exposed controls.

However, other institutions have recently reported a correlation between exposure to DES in the womb and increased rates of genital tumors, abnormal semen quality, and low sperm count.

DES was used during the early 1950s to prevent miscarriages and other problems of pregnancy. The hormone was later shown to have no effect on these problems, and its use was discontinued.

In 1971, physicians found a rare form of vaginal cancer in women whose mothers had taken DES during their pregnancy.

According to Kessler, the hormone was given to over one million women. That means that at least as many children were exposed to it in the womb, 50 percent of them male, he said.

Men who know they were exposed to DES and who desire a free evaluation should contact the division of urology, 497-5746.

Dr. Charles E. Rackley, director of the Specialized Center of Research for Ischemic Heart Disease, will present the 14th John Kent Lewis Memorial Lecture on Monday, May 14, at Stanford University School of Medicine

The public talk, which will begin at 4:30 p.m. in the school's Fairchild Auditorium, is entitled "Clinical Application of Hemodynamic Studies in Patients with Acute Myocardial Infarction."

Rackley is also professor of medicine at the Specialized Research Center at the University of Alabama in Birmingham.

He has served as director of the center since 1975, and he previously directed a myocardial infarction research unit, and a research and training center for cardiovascular disease. Both of these centers are at the University of Alabama.

Rackley received his M.D. from Duke University in 1958. He is a three-time recipient of the Susan and Theodore Cummings Award of the American College of Cardiology.

The John Kent Lewis Lectures are presented annually in honor of the late professor of medicine and chief of the Stanford Medical Service at San Francisco General Hospital. A 1922 graduate of Stanford Medical School, Lewis was a pioneer in heart research. He died in 1961.

Verla Lunger has been named Stanford University Hospital's Employee of the Year.

Lunger, a unit clerk on the Medical Intensive Care Unit (M-ICU), was presented with the 1979 Dr. Thomas A. Gonda Award, which is annually given to the most outstanding employee in Stanford Hospital and Clinics.

An 18-year hospital employee, Lunger is the fourth recipient of the Award which is named after the former director of Stanford Hospital and currently chairman of the Department of Psychiatry and Behavioral Sciences at Stanford Medical School.

"Verla has provided outstanding support to both management and staff," commented hospital administrator Gary Mecklenburg. "Her attitude and genuine concern for individuals and her unit are reflected by her high productivity and sensitivity to the needs of others."

Also honored during the hospital and clinics' 21st annual awards banquet recently were five employees who were presented with special service awards. They are Emil Strom, Ruth Ware, Molly Palmer, Kay Rupp and Helen Rantz.

A total of 394 other employees were given service pins ranging from five to 30 years. In all, these employees have given 2,980 years of service to the hospital and clinics.

Lunger joined the hospital staff in 1961 when her husband Bill was laid off from work shortly after they moved to the Palo Alto area from Pennsylvania.

Initially, she "floated" between intensive care and another nursing unit. Then, except for a six month stint in surgery, she has worked continuously in intensive care.

"I like the unit very much," commented Lunger, a mother of two children. "It's a challenge and it provides me with a variety of unexpected things. I also like the people I work with because they are professional, dedicated and compassionate."

"The Brain as an Imperfect Machine," the second in a series of three public lectures on the human brain, will be presented by Dr. David A. Prince on Wednesday, May 9, at Stanford University School of Medicine.

The lecture begins at 7:30 p.m. in Fairchild Auditorium.

Prince, who is professor and chairman of the Department of Neurology at Stanford, will discuss medical advances in the understanding of epilepsy and other brain disorders.

Prince is a widely-recognized researcher of epilepsy, a disease in which the victim suffers seizures or convulsions due to abnormal brain activity.

Last year he was awarded the Lennox Prize by the American Epilepsy Society for his contributions in the field. He is also a past recipient of a John Simon Guggenheim Memorial Foundation award for his contributions in researching abnormalities of single nerve cells in epilepsy.

Prince received his M.D. from the University of Pennsylvania in 1956. He was on the neurology staff at Mt. Sinai Hospital in New York City before joining Stanford in 1962.

Prince's address is one of three Spring Progress in Medicine Lectures being presented by Stanford neuroscientists. The next lecture Wednesday, May 16—"How Do Monkeys Use Their Heads?"—will be given by Dr. James H. Dewson III, associate professor of speech and hearing sciences.

The Progress in Medicine Lectures are presented by the dean and faculty of Stanford Medical School, and by the Stanford Medical Center Council.

STANFORD—

A nerve growth hormone, purified by Stanford University scientists 12 years ago, may exert a more profound influence on nerve cell development than scientists had previously thought.

The hormone, called nerve growth factor (NGF), may modify the cell's genetic program so that it begins to produce new and greater amounts of proteins, according to Dr. Eric Shooter, professor and chairman of the neurobiology department at Stanford University School of Medicine.

Previously, it was thought that NGF exerted its actions through receptors on the surfaces of nerve cells which bound the hormone.

Recently, however, Shooter and medical student Bruce Yankner have found that NGF is also present in the cell nucleus, mixed with the genetic material.

Shooter explained that there is evidence that the nerve cell early in development is a "generalist," capable of producing a wide range of proteins and performing a wide variety of functions.

However, after the cell matures, it becomes a "specialist," with a definite set of proteins to produce and functions to perform.

NGF may be involved at the early stage in determining which proteins the cell produces, and hence, what kind of specialist it becomes.

It thus may "reprogram" the cell, said Shooter.

A report of his and Yankner's work appears in the March issue of the *Proceedings of the National Academy of Sciences.*

NGF was discovered in a variety of tissues and species in the early 1950s by an Italian scientist, Dr. Rita Levi-Montalcini.

She showed that when NGF is injected into nerve ganglia of the chick, it causes them to balloon up to 12 times their normal size, and stimulates tremendous growth of nerve fibers.

If antibody against NGF is given to eliminate the hormone, growth of the sympathetic nervous system is stopped completely.

Much remains to be learned about NGF, for example, its presence in humans has not yet been confirmed.

However, it is providing information on how other, similar hormones work.

NGF is specific for sympathetic and some sensory nerves. Recently, other factors have been discovered which stimulate the growth of different nerves and some tissues.

NGF is similar in structure to insulin, a hormone well known for its ability to facilitate transport of sugars from the blood stream into the cell. Both NGF and insulin seem to be made in a similar fashion, cleaved from a larger molecule by a digestive enzyme.

Other investigators have found insulin in the nuclei of rat liver cells suggesting that it too may interact with the genes.

- more -

Shooter said that future research at Stanford will center on determining how NGF gets into the nuclei of nerve cells, and how it acts.

Recently, he and his associates have found that NGF binds to two different receptors on the surfaces of nerve cells. Only one of the receptors is involved in the stimulatory effects on growth.

Binding to receptors may be an important first step in bringing NGF into the cell, said Shooter.

Binding may stimulate the cell membrane to engulf NGF and its receptors, similar to the way in which an amoeba swallows its food.

Once inside the cell, NGF could migrate to the nucleus and mix with genetic material.

This model is supported by the fact that NGF can be seen under the microscope inside mature nerve cells, he said.

Research on NGF may have a bearing on the understanding, not only of nerve development, but of certain human diseases, said Shooter.

For example, some scientists believe that neuroblastoma, a common brain tumor in children, results from abnormalities in the action or production of a human NGF.

However, treatment of these tumors with NGF isolated from the mouse so far has been unsucccessful, said Shooter.

"We need to understand better how it acts before we begin to treat disease," he said.

The research at Stanford is supported by grants from the National Institute of Neurological Diseases and Stroke and the Alfred P. Sloan Foundation.

STANFORD—

A memorial service for Dr. Harold K. Faber, an internationally known Stanford pediatrician, will be held Monday in San Francisco.

Dr. Faber, professor of pediatrics emeritus at Stanford University School of Medicine and a founder of the Children's Hospital at Stanford, died Friday (April 27) in San Francisco.

He was 94.

A noted polio researcher, Dr. Faber was professor of pediatrics and chairman of the department from 1923 until his retirement in 1949. He had also served as pediatrician-in-chief of Stanford University Hospital in San Francisco.

Dr. Faber was born in Westfield, New York, and took his A.B. at Harvard and his M.D. degree at the University of Michigan. Prior to joining Stanford he was resident pathologist, Babies Hospital in New York, and a Fellow of the Rockefeller Institute for Medical Research.

He served as president of the American Pediatric Society in 1946. He contributed over 140 scientific papers on pediatrics to leading medical journals, and in 1956 he received the Society's prestigious Howland Medal.

In 1917, in collaboration with the Reverend D. Charles Gardner, Stanford University chaplain, and members of the Campus Auxiliary of the Stanford University Clinics, then located in San Francisco, they conceived the idea of establishing a home-away-from-home for convalescent children.

This unique concept, was in time, to develop into the formal founding of what was then known as the Stanford Home for Convalescent Children ("Con Home" to old timers) in 1919. The opening of the Leland Stanford residence in 1920 was the first unit of what is today the Children's Hospital at Stanford.

Dr. Faber served as medical director of the Stanford Convalescent Home from 1923 to 1956. In 1942 he was appointed to the board and elected vice-president in 1946. He served as a trustee until 1965.

Dr. Faber lived in San Francisco. His wife, Mary, died earlier this year. There are no survivors.

The memorial service Monday will be at 11 a.m. in St. Mary the Virgin Episcopal Church, 2325 Union Street.

For those wishing to make a contribution in Dr. Faber's memory, donations were suggested to the Faber Professorship Fund at Stanford University, the Faber Pediatric Library Endowment Fund at Stanford, the Institute of Medical Sciences in San Francisco, or the San Francisco Symphony Association.

Dr. Arno G. Motulsky of the University of Washington, Seattle, will present the sixth annual Windsor C. Cutting Memorial Lecture at Stanford University School of Medicine on Thursday, May 10.

Dr. Motulsky is professor of medicine and genetics, and director of the Division of Medical Genetics and the Center for Inherited Diseases at the University of Washington. He will discuss "Human pharmacogenetics and ecogenetics" at 4:15 p.m. in Fairchild Auditorium.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the department of pharmacology, and is supported by private contributions. It honors the memory of Dr. Cutting, professor and former chairman of the department.

Dr. Cutting, who died in 1972, also served as dean of Stanford Medical School, 1953-57, and as dean of the University of Hawaii Medical School, 1963-71.

The lectures are presented annually by speakers prominent in the field of pharmacology, and they are open to the medical community and to the public.

Dr. James B. Snow, Jr., internationally-known specialist in cancer of the head and neck, will deliver the third George Kiperash Lecture, Tuesday, May 8.

His talk, entitled "Randomized Preoperative and Postoperative Radiation Therapy of Head and Neck Carcinoma," will be given in the Fairchild Auditorium of Stanford University Medical School at 8:00 p.m.

The lecture is open to the public and is sponsored by the Medical School's division of otolaryngology.

Snow is professor and chairman of the department of otorhinolaryngology and human communication at the University of Pennsylvania School of Medicine in Philadelphia.

Snow is best known for his work in surgical treatment of head and neck cancers and in the management of ear diseases. He is the author of over 100 scientific publications.

He has been an active contributor to the continuing education programs of the American Academy of Otolaryngology and the American College of Surgeons.

He has served as chairman-secretary of the U.S. Group of Collegium, an international honor society of otolaryngologists, and currently is chairman of the surgical committee of the Radiation Therapy Oncology Group.

A graduate of the University of Oklahoma, Snow received his medical doctorate from Harvard University in 1956.

The Kiperash Lecture was established to bring national and international figures to Stanford and to enhance continuing education and residency training.

It is named after George S. Kiperash, Jr., Stanford patient and native of San Jose. Kiperash is in the ranching business and is associated with Modern Ice and Cold Storage Co. of San Jose.

STANFORD—

Mother's milk is a "dowry of immunity," which protects newborn infants from a contaminated world, according to Dr. Alan E. Beer, chairman of the department of obstetrics and gynecology at the University of Michigan.

If infants did not receive "ready made" immunity in the form of antibodies and lymphocytes from their mothers, they might succumb to massive infection before their own immune defenses developed, Beer said.

Beer spoke during a three-day conference on nutrition for the high-risk infant at Stanford Medical School's Fairchild Auditorium Tuesday, June 26.

The conference, for continuing education of health professionals, was sponsored by the department of pediatrics.

Human milk actually is a suspension of immune system cells in a highly nutritive medium, Beer said. Milk has been found to react against bacteria, mumps, measles, rubella, herpes and other virus infections.

Several studies have shown lower mortality rates among breast-fed infants compared with those who received only artificial formulas.

Breast-fed infants have fewer infections, fewer milk-related allergies and skin rashes, and a lower incidence of sudden infant death syndrome, or crib death, Beer said.

In addition, studies in animals suggest that mother's milk can pass resistance to tumors on to the infant.

The immune system cells provided by maternal milk are not transported into the infant's blood stream, but seem to give protection at the intestinal barrier, he said.

Immune cells marked by fluorescent dye can be detected in the gut lining of baby animals for as long as three weeks following feeding. The high buffering capacity of milk protects the cells from digestion, said Beer.

These studies are "beginning to mount cogent arguments that milk-dispensed immune cells can fulfill important immunologically protective functions which are denied the formula-fed infant," he said.

Physicians have begun to recognize the value of psychological bonding between mother and infant at birth. Similarly, Beer recommended that "microbial bonding" be allowed to occur in the delivery room.

By breast feeding their babies soon after birth, and perhaps even by kissing them, mothers can "innoculate" them against organisms which their bodies already have anticipated, he said.

STANFORD—

Stanford University Hospital has been cited for violations of state health and safety standards, one involving the use and storage of a chemical carcinogen.

The violations, which carry a total fine of $1,800, were discovered during a routine inspection in March by the State Division of Occupational Safety and Health (DOSH), according to Hilary Ryniewicz, director of safety and security at the hospital.

Ryniewicz said DOSH inspectors found that a registered carcinogen, alpha naphthylamine, was improperly stored in the infectious disease laboratory. However, this chemical had been rarely used.

In addition, some laboratory personnel, according to DOSH, had not been formally instructed concerning the dangers of carcinogens.

The inspection, Ryniewicz said, also revealed five general violations that do not carry fines.

The inspectors found that the restroom facilities available to the hospital blood bank were inadequate for the number of employees.

They also cited the need for shower facilities in closer proximity to the clinical laboratories where some personnel handle corrosive materials, and the need for improved ventilation in a paint spray booth in the paint shop.

The problems are being corrected, said Ryniewicz. And the alpha naphthylamine in the infectious disease laboratory has been removed because there are other safe compounds that can be used in its place.

STANFORD—

Stanford University has been awarded a grant of $426,000 for three years by the Henry J. Kaiser Family Foundation to support studies on improving the quality and efficiency of teaching general internal medicine.

Dr. Robert J. Glaser, president of the Foundation, recently announced the award in a letter to Dr. Kenneth L. Melmon, chairman of the Stanford Medical School's department of medicine.

The grant focuses on three areas:

- expanding a program to train physicians for teaching careers in general internal medicine;
- evaluating and improving the effectiveness of bedside teaching;
- studying the costs of running a department of medicine.

According to Dr. Harold C. Sox, Jr., assistant professor of medicine and director of the division of general internal medicine, the new grant reflects the need for more primary care physicians while controlling the skyrocketing costs of medical care.

General internists are often the first physicians to see patients with new medical problems, Sox says. They are responsible for making the initial diagnosis, coordinating the contributions of subspecialty consultants, and providing continuous and comprehensive patient care.

As a result, "general internists have a great deal to contribute to new knowledge about how medicine is practiced and how it can be improved," he says.

Stanford began a program to train teachers of primary care physicians three years ago under a pilot grant from the Kaiser Family Foundation.

Under the present grant, four Kaiser fellows will be trained in essential clinical teaching skills, Sox says.

They also will be prepared for careers as clinical investigators in health services research, he says. Their research efforts will add to several on-going projects in the division of general internal medicine, such as developing methods of screening patients with chest pain for heart disease, and evaluating the use of computers in making clinical diagnoses.

The Kaiser grant also supports an evaluation of current clinical teaching in the department of medicine.

Dr. Kelley Skeff, a physician and graduate student in education, and a former Kaiser fellow, has developed a questionaire for evaluating bedside instruction given by faculty physicians. The results will then be provided to the faculty as feedback, and the impact on teaching performance will be determined.

"The implications for improving patient care, by improving teaching, are obvious," Sox says.

The goal of the third study, on costs, is to develop a business approach to the financing of medical education, according to Melmon.

Dr. David Chin, a fellow in medicine and student in the School of Business, will lead a study which will "dissect" the activities of department members, and define how these activities are paid for. Chin will be assisted by faculty members in the Schools of Medicine, Business and Economics.

"In the past, academic medicine felt it deserved to get anything it needed to do anything it wanted," Melmon says.

But attitudes are changing. The public still supports medical schools, but "it is clear it no longer can afford them at present levels."

In a time of uncertain and shrinking support from the federal government, medical schools must control more carefully what they spend, and seek alternative means of financing medical education, he says.

The study of the department of medicine is a first step in that direction.

STANFORD—

A promising new technique to help cancer specialists visualize tumors and the effects of treatment longer than is now possible is being developed by a Stanford University scientist.

The scientist is Dr. Stuart Young, an assistant professor of radiology. Young has been studying compounds known as contrast agents.

When injected into the body, these agents enhance the density differences between normal and cancerous tissues, so tumors appear as white images on x-rays or computed tomography (C.T.) scans, Young said.

C.T. scans enable physicians to reconstruct a three-dimensional picture of the body from x-rays, with the aid of a computer.

Available contrast agents or dyes are useful for brief periods lasting only a few minutes, since these substances quickly leak into both normal and abnormal tissues, he said.

Using compounds made of large molecules in combination with metallic salts, Young has obtained C.T. scans and x-rays highlighting inflammatory tumors and abscesses in rabbits for as long as seven weeks.

"Within days and for several weeks following injection of the agents we see dense rings around tumors and abscesses," he explained.

"When we examine the tissue through the microscope, we find the visible particles in white blood cells called macrophages," he continued.

Macrophages are cells produced in response to inflammatory tumors and they scavenge foreign particles as part of the body's defense mechanism.

The macrophages probably absorb the macromolecules and migrate into the tumor where they cause it to appear as dense material on the C.T. scans or x-ray, he explained.

The work is still highly experimental, he noted, and several substances are being tested that show some promise. Once suitable compounds are found, "it might even be possible to tag the macromolecules with therapeutic substances which could be delivered directly to the tumor," he suggested.

The compounds Young has tested in rabbits have toxic components, limiting their use in humans.

Additional substances being examined by Young and his colleagues are microemulsions that also appear to collect in macrophages. Another large molecule being tested is albumin, a protein found in many animals.

Young's interest in contrast agents developed from his work on controlling local blood flow with pharmaceutical and mechanical agents.

If flow could be increased to tumors, he said, therapeutic agents could be selectively delivered to the growths.

If flow could be decreased in tumors, application of a device such as an ultrasonic probe could locally heat the tissue, possibly devastating some cancers, he added.

Young presented his preliminary results on contrast agents at a meeting of the Association of University Radiologists last month.

His work on contrast agents is funded by the Cancer and Medical Research Foundation of Berkeley. The National Cancer Institute and the American Cancer Society also provide support.

STANFORD—

When Carolyn Adorni, 26, discovered that she had cancer of the lymph nodes, known as Hodgkins disease, her doctor in Eureka referred her to Stanford Medical Center where she now is undergoing an 18-week course of radiation therapy.

Like many cancer patients from out of town, Carolyn not only had to come to terms with her disease, but faced the additional hardship of finding housing in the expensive and crowded midpeninsula.

But Carolyn is more fortunate than many patients in her predicament. She was chosen to participate in a pilot program of subsidized housing for long-term outpatients at Stanford University Medical Center. The effort was initiated and supported by the Assistance League of Santa Clara County, a national non-profit volunteer service organization.

Kay Clair, chairwoman of the Assistance League's HOME (Housing of Medical Emergencies) committee, describes how the project began.

"Many of our members had personal experiences with family and friends with cancer. Being at the hospital day after day, seeing relatives living in the waiting rooms, we became aware of the desperate need for patient and family housing near the hospital," she recalls.

Stanford Medical Center has no housing accomodations for long term outpatients or families of inpatients. The problems associated with this are "one of the hidden costs of medical care," according to Flora Finney, assistant director in the division of clinical social work.

"The cost of staying in a motel for weeks on end, renting a car to go back and forth to the hospital for daily treatments, and eating out several times each day can be astronomical," adds Clair.

The emotional costs may be equally high for patients and families dealing with serious illness far from home.

About four years ago the HOME committee began examining possible solutions to the patient housing problem, writing to several major medical centers across the country to get ideas.

Previous attempts at Stanford such as finding moderately priced rooms for patients in private homes had not been successful, reports Clair, in part because "even the most generous people are unable to cope with serious illness in their home for any length of time."

Local apartment complexes are leery of the turnover involved in rentals of a few weeks or months duration, Clair explains, and the demand from local industry keeps them constantly full.

- more -

After many months of investigation, the Assistance League found two one-bedroom apartments in the Oak Creek apartment complex just across Willow Road from the hospital.

Clair feels that one reason Oak Creek Apartments was receptive to their cause was "because their administrator died of cancer last year and they saw the many months of treatment required."

"Our apartments are aimed at people caught in the middle of the financial squeeze," notes Clair, "particularly those not receiving financial assistance of any kind."

Patients are screened by social workers from the oncology and radiation therapy divisions, and those recommended may stay for up to nine weeks, with a minimum charge of $10 per day, "substantially below the rates of most motels in the area," Clair points out.

Stays are limited to nine weeks per patient in order to make them available to a greater number of people, according to Finney.

Carolyn and her sister, Mona Vaughn, are grateful for the help they have received.

In the small but comfortably furnished living room Carolyn explained some of the conveniences.

Receiving treatments four days a week, she continually feels drained and nauseated, she said, so the proximity of the apartment to the hospital is a great advantage. In fact, one of the other tenants was actually able to walk the distance daily, she said.

"Because of my nausea," she added, "I can't eat much and being able to cook at home what I want when I want it is wonderful."

Oak Creek apartments are close to public transportation and the Stanford Shopping Center while providing quiet and peaceful surroundings, Carolyn pointed out, and facilities such as the swimming pool have given Mona something to do.

On weekends, when Carolyn gets a break from her treatment schedule, she and Mona make the six-hour drive home to Eureka to join their husbands and Carolyn's four-year-old son.

Before they moved into the apartment, they had to switch motels each week when they returned and found that their previous motel had filled up.

"It's been great," said Carolyn, but she is apprehensive about their next move when the nine week rental ends. "I guess we'll just have to go back to staying in motels unless something else comes up while Carolyn completes her last six weeks of therapy," said Mona.

Since February when the program began, seven patients and their families have been helped but "this is just a drop in the bucket compared to the need," Clair admits.

Presently, there are always at least five patients on each waiting list and this doesn't include patients from other divisions such as cardiology and dialysis, notes Clair.

STANFORD—

Dr. Orland Soave, who retired earlier this year as director of the Division of Laboratory Animal Medicine at Stanford University, has accepted a position with the National Institutes of Health in Bethesda, Maryland.

Soave will be an expert consultant in biomedical sciences to the Library of Medicine and will help develop a program on collection and computer storage of biological data on experimental animals.

The appointment becomes effective July 1.

"The Laboratory Animal Data Bank (LADB) will provide information on the physiology, anatomy, pharmacology, toxicology, pathology and diseases of animals used for cancer research, toxicology, drug testing and nutrition," Soave said.

"The data bank will be of great value to pharmaceutical companies, research institutes, and universities in comparing their test results with the normal biological values of thousands of other animals tested," he added.

Soave announced his retirement at Stanford in March after 19 years of service. He is a specialist in veterinary medicine and viral disease in animals.

In the early sixties he served as a member of the Animal Care Panel of the National Institutes of Health which developed standards for animal care in the nation's biomedical research facilities.

STANFORD—

Stanford University School of Medicine presented 142 degrees during its annual commencement exercises Sunday, June 17.

The ceremonies also honored seven medical school faculty members for outstanding achievements in teaching.

Medical degrees were presented to 80 men and women. The medical school also awarded 25 Ph.D's, 33 masters' and four bachelor of science degrees.

The diplomas were presented during ceremonies in Stanford Medical School's Grant Courtyard following the university's 88th annual commencement at Frost Memorial Amphitheater.

Dr. Myer H. Rosenthal, assistant professor of anesthesia and director of intensive care medicine at Stanford, was singled out by the medical graduates as recipient of the Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine.

Five other faculty members voted by the medical students to receive Henry J. Kaiser Awards for excellence in teaching were Drs. Lawrence H. Mathers, assistant professor of structural biology; Norman Blank, professor of radiology; Robert Neil Sladen, assistant professor of anesthesia; Keith Marton, assistant professor of general internal medicine; and Sylvia H. Friedberg, lecturer in structural biology.

The Henry J. Kaiser Award for outstanding and innovative contributions to medical education was presented to Dr. Roy H. Maffly, professor of medicine.

It marked the fourth time that Maffly had received a Kaiser Award for either preclinical or clinical teaching. He was also the recipient of the Bloomfield Award in 1977, and the Outstanding Teaching Award by the medical graduating class of 1971.

Robert L. Simpson, a registered physical therapist at Menlo Medical Clinic, was awarded the annual Lucille Daniels Recognition Award for Outstanding Contributions to Phyical Therapy. Simpson is a clinical instructor in the medical school's Division of Physical Therapy.

The medical school commencement address was delivered by Dr. Richard Selzer, a surgeon and author in New Haven, Conn., and a member of the Yale Medical School faculty.

Diplomas were presented by Dr. Lawrence G. Crowley, acting vice-president and dean of the medical school. He was assisted by Dr. William P. Creger, professor of hematology, and Barbara E. Kent, adjunct professor of physical therapy.

STANFORD—

A study recently completed at Stanford University Medical Center indicates that 25 percent of the patients seen in the General Medical Clinic do not know the precise purpose of the medications they take and 38 percent are misinformed about how frequently to take them.

Fewer than 10 percent of the patients in the study knew all four components useful for proper medication consumption and reporting: the name, dose, frequency and purpose.

However, only 7 percent of the patients wanted more information about their medical problems and only 2 percent wanted more complete information on their medications.

Dr. Peter Rudd, assistant professor of medicine, and two research assistants, Viviana Tul and Barbara Beilstein, conducted the survey of patient knowledge as part of a larger study on doctor/patient communication.

"Communication with the patient is one of the most important components of being an effective clinician," says Rudd. "But teaching physicians how to communicate effectively is difficult," he adds.

Rudd and his assistants tested one method of changing physician behavior using the patients as self-advocates.

The study results showed that physicians responded minimally to patients' suggestions to perform additional services. However, physicians responded favorably to similar suggestions from clinic staff offered in problem-oriented sessions, according to Rudd.

"The best way to induce changes in physician behavior remains controversial," Rudd says. "But improving doctor/patient communication would be one critical area for applying new methods."

Rudd presented the findings at the national meeting of the American Federation for Clinical Research in Washington, D.C. last month.

STANFORD—

Dr. I. Robert Lehman, professor of biochemistry, has resigned as chairman of the department of biochemistry at Stanford University School of Medicine.

The resignation, effective August 31, was announced Wednesday, June 13, by Dr. Lawrence G. Crowley, Acting Dean of the Medical School.

Lehman, chairman of the department since 1974, said he is relinquishing his administrative responsibilities to return to teaching and research.

Crowley said that a committee headed by Dr. Eric Shooter, professor and chairman of the department of neurobiology, has been appointed to search for a successor.

Lehman is best known for his research on the mechanisms of DNA synthesis, repair and recombination.

An alumnus of Johns Hopkins University, Lehman received his Ph.D. in biochemistry in 1954.

He was a fellow at the McCollum-Pratt Institute of Johns Hopkins, and was on the faculty of the department of microbiology at Washington University School of Medicine in St. Louis, before coming to Stanford in 1959.

The author of numerous scientific publications, Lehman has served as associate editor of the *Journal of Biological Chemistry*. He is a fellow of the American Academy of Arts and Sciences, and is a member of the National Academy of Sciences.

Lehman has also received the Henry J. Kaiser Award for excellence in teaching at Stanford Medical School.

STANFORD—

Dr. Thomas A. Stamey of Stanford University School of Medicine, has been selected as a Royal Society of Medicine Foundation Visiting Professor.

Stamey, professor of surgery and head of the division of urology, is one of three awardees chosen by the New York based Foundation whose primary purpose is to sponsor exchange of medical information between the United States and Great Britain.

As a visiting professor, Stamey will spend one month in Britain during May, 1980, under the auspices of the Royal Society of Medicine, and he will receive a commemorative medal.

During his stay, he will present lectures before the Society in London and will confer with British colleagues.

Stamey was nominated for the honor by the section on urology of the Royal Society of Medicine. He is noted for his extensive research of recurrent urinary infections in women.

Urinary tract infections are the most common bacterial infections in humans, according to Stamey, and his study has focused on why some women are more susceptible than others.

He has found that susceptible women lack certain antibodies (molecules responsible for the body's bacterial defense mechanism) in the vaginal area, leaving them open to infection.

Stamey received his M.D. degree from Johns Hopkins University School of Medicine and has been at Stanford since 1961.

He is the first physician from the West Coast selected to participate in the visiting professor exchange, according to the Foundation.

STANFORD--

A device developed by a team of engineers and anesthesiologists at Stanford University is being tested for its ability to make surgery safer.

The device apparently has solved the problem of electrocautery interfering with monitoring equipment during surgery.

Electrocautery is the use of a high voltage electric current to cut through tissue and stop bleeding by cauterizing, or searing closed blood vessels.

The electric current is delivered through a thin metal probe with an insulated handle, called a surgical cauterizing knife.

While electrocautery has enabled physicians to perform major surgeries of the heart, skeleton and brain by stopping bleeding which otherwise would be uncontrollable, the technique wreaks havoc with the electronic monitoring of vital functions.

"The surgical cauterizing knife is like a gigantic radiotransmitter, sending potent radio waves from the point of contact throughout the patient's body," says Dr. William New, assistant professor of anesthesia at Stanford University School of Medicine.

"It creates overwhelming electrical interference of any signal (EKG, blood pressure, etc.) which attempts to monitor body function during the operation," he says.

Often, the surgeon turns on the current for as long as two minutes, during which time the anesthesiologist has to "fly blind," with nothing but the most primitive means, such as taking a pulse, of monitoring the patient.

Deaths during surgery are rare, but it has been well documented that they occur when patients are not being monitored, or when the monitors are useless (during electrocautery, for example), says New.

Drs. New and Mark Yelderman, also assistant professor of anesthesia, and four masters candidates in electrical engineering now have developed a modification of monitoring techniques which enables them to filter out the interference caused by electrocautery.

The students, Ed Hesler, Jeff Leddy, John Cioffi, and John Brennan, designed the new equipment as part of a masters degree project in computer applications under the direction of Professor Bernard Widrow, of the Stanford Electrical Engineering Department.

About 10 years ago, Widrow demonstrated that computers can be programmed in such a way that they can automatically "learn" to eliminate certain portions of an electrical signal, leaving the rest intact.

With the emergence of the microprocessor, it became practical to apply this computer capability to clinical medicine.

The students designed circuits which collect the EKG signal, or electrocardiogram, while eliminating much of the interference.

Recently, the equipment was tested successfully in the operating room, says Yelderman. A clear EKG signal was obtained even when the cauterizing knife was being used.

The device promises to make surgery safer, he says, because anesthesiologists will be able to monitor patients continuously.

The Stanford group plans to conduct further clinical trials this summer. According to Yelderman, the device could be commercially available within two years.

A SPECIAL REPORT—ARTHRITIS

STANFORD—Though not a killer like cancer or heart disease, arthritis is said to cause more pain, more work loss, and more poor functions in daily life than any other human illness.

An estimated 32 million Americans suffer from some form of arthritis, and over five million are disabled by the disease.

As yet there is no cure, but scientists are beginning to find clues to the factors which may cause arthritis. In addition, the combination of drugs, exercise, and sometimes surgery can control the symptoms and often alter the course of the disease.

The following article, the first in a three-part series on arthritis treatment and research at Stanford University Medical Center, tells the story of a couple who have "fought the good fight" against their disease.

Mailed Wednesday, July 25, 1979

Part I—Never Give Up the Fight

John Gothan celebrates his 30th anniversary this year. It is not a wedding anniversary, but a count of the years he has lived as a victim of poker spine. The disease, known by the scientific name of ankylosing spondylitis, is an insidious form of arthritis striking the back and often immobilizing its victims.

The disease has compressed and fused the vertebrae of John's back, so that he can turn only with difficulty, by swinging his whole torso around. And he is shorter. "I used to be five foot eleven," he says. "Now I'm five foot three."

His wife, Ruth, suffers from rheumatoid arthritis and vasculitis, an inflammation of blood vessels. The arthritis has attacked her hands, deforming the joints so badly she has difficulty performing the kitchen tasks she once found easy.

"Imagine what it would be like going through life with a catcher's mitts on your hands," says John. "That's what it's like for Ruth."

His wife agrees with the analogy, except to add that the clumsiness caused by the disease is accompanied by almost constant pain. "I have to laugh at the television commercials that talk about the minor pains of arthritis," she says. "I have the pain, but I have never felt it was minor."

Yet neither John nor Ruth Gothan consider themselves invalids. John had to retire at age 40, but he and his wife keep busy, and they visit frequently with several family members who live near their San Mateo home.

The Key is Good Medical Care

The key to coping with arthritis is good medical care, physical therapy, and most important, a cheerful and determined attitude, they say.

"Never give up the fight" is John's motto, and it has seen him through the years he has had the disease.

When John first got ankylosing spondylitis, doctors didn't know what it was. Radiation and heat lamp treatments had no effect, and bed rest only made it worse. Today, as a patient at the Palo Alto Veterans Administration Medical Center, he receives drugs to reduce the inflammation of his joints and relieve the pain.

John is also taking cortisone, a hormone produced by the body which reduces the immune responses thought to underlie the disease. Cortisone has several possible side effects, including infection, bone deterioration, and rarely, mental difficulties, and therefore is given only in low doses. But he says, "I don't regret taking it. It was the lesser of two evils. I took it in the hope that the doctors someday will find something better."

In 1976 John received an artificial hip joint, made of stainless steel and plastic, to replace the right hip which had pained him since 1949, and forced his retirement 16 years later. "Today, my leg is better than it has been since 1959," he says.

Ruth, too, had surgery to replace the knuckle joints in her right hand. The fingers have straightened out, there is less pain, and she has regained some function in the hand. She is a patient of Dr. Melvin Britton, a rheumatologist at the Palo Alto Medical Clinic.

Day Begins with Exercise

An important part of every day at the Gothan household begins with exercise. Ruth does clenching and extending exercises to keep her fingers supple. John does isometrics and stretching exercises to retain as much flexibility as possible in his back, and to strengthen the ligaments, muscles, and bones of his arms and legs.

"We have to do this every day," says Ruth. "The minute you stop, the muscles begin to deteriorate."

The exercise time also gives the Gothans a chance to work out their frustrations. "We do a lot of yelling," admits John, smiling good-naturedly at his wife.

"I guess we are easily pacified," he adds. "We have a very full life. And we have learned to adapt."

Next... the attack of the body upon itself.

Editors: This article, the second in a three-part series on arthritis, concerns advances made by researchers at Stanford University Medical Center in understanding the disease as an "attack of the body upon itself."

Part II—New Hope for Painful Joints

STANFORD—Research at Stanford University Medical Center is improving understanding about the causes and development of rheumatoid arthritis that may one day lead to prevention or cure.

For several years scientists have believed that diseases such as rheumatoid arthritis involve an attack of the body on itself.

The theory is that in these diseases, the immune system has gone awry, and produces antibodies against the body's own tissues.

Many of the current therapies for rheumatoid arthritis support this theory.

Severe cases of the disease are treated with drugs such as azathioprine and cortisone, which suppress immune responses. Less powerful drugs which affect immunity, including gold compounds and penicillamine, can reduce inflammation and other rheumatoid symptoms in some patients.

At Stanford University Medical Center, radiation treatments are being tested in patients with severe forms of rheumatoid arthritis who are not helped by conventional therapy.

The program, directed by Dr. Samuel Strober, associate professor of medicine, developed out of observations that radiation therapy causes a reduction in some of the body's immune defenses, presumably by killing certain types of white blood cells, without increasing susceptibility to most infections.

Strober's group recently reported limited success in treating six patients with radiation, but the researchers caution that the procedure is still experimental.

While most of the treatments for rheumatoid arthritis suppress the disease, they do not provide a cure. In fact drugs such as cortisone and azathioprine may result in side effects in some patients, including toxic reactions, infection, bone degeneration, and the development of other diseases such as cancer.

Hereditary Predisposition

Recently, the discovery that several forms of arthritis are linked to the presence of markers on white blood cells, has generated considerable excitement among scientists.

These markers, called human leukocyte antigens (HLAs), enable white blood cells to distinguish between body tissues and foreign materials such as bacteria, viruses, and organ transplants.

When a foreign agent is identified, an immune response is mounted against it.

But the markers also are associated with an inherited susceptibility to diseases such as multiple sclerosis, juvenile diabetes, acute lymphocytic leukemia, Hodgkin's disease, as well as arthritis.

Not everyone who carries the markers will get disease. But they are at greater risk, particularly after being exposed to environmental factors, such as bacterial or viral infections.

Thus, persons who inherit certain white-cell markers are like preset fuses. An infection simply lights the fuse that explodes into disease.

The implications of this discovery are enormous, Stanford scientists believe. The HLA system may one day provide a means of screening persons susceptible for various diseases.

If an infectious agent is found to be responsible, these people could be innoculated against it, thereby preventing the disease. Alternatively, the immune system could be manipulated to correct the "defect" which permits disease to develop.

The strongest link between a hereditary disposition and disease is that which has been found between a marker called B27 and ankylosing spondylitis, the so-called "poker spine" disease.

B27 is carried by seven percent of the white population, and by a slightly lower percentage of blacks. However, it is found in well over 90 percent of patients with the disease.

Ankylosing spondylitis was once believed to be a rare disorder, afflicting perhaps one in 1,000 whites, the majority of them male. But a 1975 survey by Stanford immunologists James Fries and Andrei Calin revealed that 20 percent of the males and 17 percent of the females who carried the marker B27 had the disease—10 times the expected frequency in males and 80 times the frequency in females.

From this study, Fries and Calin estimated that ankylosing spondylitis may strike as many as three million Americans.

The Environmental Link

The same year, the Stanford researchers demonstrated that development of at least one genetically linked disease resulted from exposure to bacterial infection.

They were investigating the case of the U.S. Navy cruiser *Little Rock*. During a tour of the Mediterranean in 1962 an epidemic of dysentery swept through *Little Rock*'s crew.

The infectious agent was identified as *Shigella* bacteria. Two weeks later 10 of the infected men developed Reiter's syndrome, characterized by inflamed eyes, swollen joints, skin lesions, and urethritis.

Calin and Fries set out to find if these men carried a marker for disease susceptibility.

In a search that took over a year to complete, the researchers tracked down six of the men. All six were afflicted with Reiter's syndrome, and five carried the marker B27. Three of the men had ankylosing spondylitis as well.

Since then, bacterial infections have been linked to other diseases caused by hereditary predisposition.

Evidence from Australia suggests that a particular strain of bacteria, *Klebsiella*, may be the culprit in ankylosing spondylitis.

Rheumatoid arthritis is associated with another hereditary marker, DRW4, and "our hunch is that like ankylosing spondylitis, it may be caused by infection in susceptible individuals," says Calin.

"So far we have no clues," he adds, "but this is where the answer will lie—in the relationship between genes and the environment."

—30—

Next—improving patient care

Editor: This article, the third in a three-part series on arthritis, features the efforts of the Stanford Arthritis Center, one of 15 in the U.S. established by Congress to improve the treatment of the disease.

Part III—Improving the Care of Patients

STANFORD—The Stanford Arthritis Center has launched a comprehensive attack on arthritis.

Several studies by health professionals at the Stanford University School of Medicine and in the community are being conducted with the aim of improving patient care.

Which tests are most valuable for making a diagnosis?

Which treatments are most effective in patients with a particular disease, age, and physical condition?

The answers to these questions can benefit patients, by avoiding unnecessary and sometimes risky procedures, and by reducing the cost of their care.

Artificial Joints

Dr. David Schurman, associate professor of surgery, is evaluating the impact of artifical joint replacement, both in terms of physical benefits and financial costs.

Last year in the U.S., 100,000 hips and 30,000 knees were replaced by steel and plastic joints. The hip operation, developed in the early 1960s, is highly successful. According to Schurman over 90 percent of patients have less pain and improved mobility following surgery.

However, despite its success, the operation costs about $8,000 and physicians have not yet determined if it is beneficial to all patients who are disabled by the disease.

The Team Approach

Dr. Andrei Calin, assistant professor of medicine, is leading a study of the usefulness of a team approach in treating arthritis.

The team may include the patient's physician, a specialist (rheumatologist or immunologist), social worker, orthopedic surgeon, physical and occupational therapists, and even a financial consultant.

"The benefits of having a variety of health professionals rather than a single practitioner are obvious," Calin says.

"However, this approach is expensive, time-consuming, and there is a concern that we may be encouraging an even greater dependence on the medical system than now exists."

Not Just for Adults

Rheumatoid arthritis is not just a disease of adults. An estimated 70,000 to 200,000 children in the U.S. exhibit symptoms such as rashes, fevers, and inflamed joints suggestive of the disease.

- more -

Fortunately, many children seem to eventually outgrow their symptoms. However, no one knows how the disease has affected their social and emotional development, not to mention physical growth.

To find out, Drs. John Miller and Gordon Williams have begun a survey of the 350 children treated at Children's Hospital at Stanford since the 1950s. So far 230 children, most of them under age 18, have been located.

Two thirds of the patients report that their disease is inactive. The researchers are now examining whether the disease has affected the ability of these children to find employment as adults.

Patient Education.

According to Dr. James Fries, associate director of the Arthritis Center, between 40 and 50 percent of patients followed by the Center have tried unorthodox remedies, such as exotic diets, flu shots, copper bracelets, and trips to U.S.-Mexican border clinics.

The Arthritis Foundation estimates that $950 million is spent on unorthodox remedies by patients every year.

"The fact that patients try these treatments and go to quacks is an indictment of medical care," says Fries. "It smacks of poor communication on the part of physicians, lack of results, and a failure to deliver hope to patients."

To improve this situation, the Arthritis Center, together with the Midpeninsula Health Service, has begun a study of the value of comprehensive patient education.

Classes involving several hundred patients provide special exercise sessions, information on medications and side effects, advice and practice on how to consult effectively with doctors and other health professionals, and group discussions on how to cope with the physical and emotional problems caused by arthritis.

The primary goals of the study, says health educator Kate Lorig, R.N., are to help patients become responsible for their own health, and to determine whether education on the management of arthritis should be provided routinely as part of patient care.

"No physician has 14 hours a day to spend in patient education," she says. "And yet, patients need to learn what they can do for themselves, and how they can get the best care at the lowest cost."

—30—

Where to find help

A directory of resources for the patient with arthritis

The Arthritis Foundation, a charitable organization committed to improving treatment, research and education of the disease, can provide a wealth of information and support services. Some of the programs include a patient treatment service, to aid patients who cannot pay for their own medical care and who are ineligible for medical insurance, and a referral list of doctors specially trained to treat arthritis.

The Northern California Chapter of the Arthritis Foundation is located at 399 Buena Vista Avenue East, San Francisco, CA 94117. Phone (415) 621-3976. Branches are located in San Jose, Oakland, Fresno, Concord, and La Selva Beach, Santa Cruz County.

Other programs are listed below:

Arthritis centers

- Stanford Arthritis Center, 701 Welch Rd., Suite 2208, Palo Alto, CA 94305. Call Pat Spitz, (415) 497-5138.
- University of California at San Francisco, Arthritis Center, 1442 Fifth St., San Francisco, CA 94143. The center provides patient education, community programs, and a resource library. Contact Sandra Lewis, program coordinator, (415) 666-1192.

Arthritis clinics

- Highland General Hospital, 1411 E. 31st St., Oakland, CA. Contact Marie Norton, patient services coordinator, (415) 621-3976.
- Children's Hospital Medical Center, 51st and Grove, Oakland, CA. Arthritis clinic for children under 18. Contact Douglas Stokes, (415) 654-5600 ext. 234, or Marie Norton, (415) 621-3976.
- John Muir Memorial Hospital, 1601 Ygnacio Valley Rd., Walnut Creek, CA. (415) 939-3000 ext. 388.

Education programs

- "Learning to Live with Arthritis," a series of classes at O'Connor Hospital, 2105 Forest Ave., San Jose, CA. (408) 298-3900 ext. 435.
- Santa Clara Valley Medical Center, San Jose. Contact Jayne Donohue, (408) 279-5552.
- "I Have Arthritis—Now What?" sponsored by the Arthritis Foundation in Santa Cruz County. Contact Brenda Schmida, (408) 688-3866, or Gaye Kihorany, (408) 426-6758.

Clubs

- Arthritis Club, Fresno Branch, Northern California Chapter of the Arthritis Foundation. Contact Elizabeth Weatherby, (209) 264-8205.
- Adolescent Rap Group for teenagers with arthritis, and Parents Club for parents of children with the disease meet at the Children's Hospital Medical Center in Oakland. Contact Herman Pugh, (415) 654-5600, ext. 266, or Marie Norton, (415) 621-3976.
- "Living it Up with Arthritis," at the Santa Clara Valley Medical Center. Contact Adrienne Herman, (408) 287-8764.

STANFORD—

Dr. Lubert Stryer, Winzer professor of cell biology, has resigned as chairman of the department of structural biology at Stanford University School of Medicine.

The resignation, effective August 31, 1979, was announced recently by Dr. Lawrence G. Crowley, acting dean of the Medical School.

"Dr. Stryer has made a very effective start in building a strong department of structural biology," Crowley said, "particularly with recruitment of several outstanding senior faculty members."

Stryer, who is also professor of structural biology, has chaired the department since its formation in 1976. It incorporated the old anatomy department, and its scope was broadened to reflect study and teaching of all levels of structural biology, from organs to molecules.

Stryer said he has resigned his administrative position to devote more time to research.

Crowley said that a committee headed by Dr. Eugene Robin, professor of medicine and acting chairman of the physiology department, has been appointed to search for a successor.

Stryer is well known for his studies of biological structure at a molecular level, studies fundamental to a better understanding of cell organization and function.

Currently he is studying the molecular aspects of visual excitation, how the absorption of light by visual pigments in the eye leads to nerve impulses.

A native of Tientsin, China, Stryer received the bachelor of science degree with honors from the University of Chicago in 1957, and the M.D. degree magna cum laude from Harvard University in 1961.

He was assistant professor in the department of biochemistry at Stanford from 1963 to 1966, and associate professor from 1966 to 1969.

He then served as professor of molecular biophysics and biochemistry at Yale University from 1969 to 1976, when he returned to Stanford.

Stryer is a recipient of the Eli Lilly Award of the American Chemical Society in biology chemistry (1970), and is a fellow of the American Academy of Arts and Sciences.

The endowed professorship he holds is named for Mrs. Frances Nunnally Winzer of La Jolla, California, a longtime major benefactor of the medical school.

STANFORD—

James H. Stanford, director of finance at Stanford University Medical Center, has resigned to become treasurer of Acurex Corporation in Mountain View.

The resignation, effective September 14, was announced recently by Dr. Lawrence G. Crowley, acting vice-president for medical affairs and dean of the Medical School.

Stanford will assume his new position in October.

"The Medical Center is very grateful to Mr. Stanford for his six years of service as director of finance," Crowley said. "He has played a very important and productive role in the overall management and planning of the center."

Stanford, 41, came to the Medical School facilities planning staff in 1967 from General Mills, Inc., in Minneapolis, where he had been assistant to the financial vice president.

He was active in the negotiations which led to the University's purchase of the City of Palo Alto's interest in the Hospital, and in July 1968 was one of three top administrators installed when the University assumed management of the Hospital.

From 1970 to 1973, Stanford served as finance director of San Jose Hospitals and Health Center, Inc.

He is a graduate of Stanford University, where he received his bachelor of arts degree (1961), and his M.B.A. from the Graduate School of Business (1964).

STANFORD—

Dr. Louis Kovitz, a retired physician from Los Altos, California, died Sunday, July 22 at Stanford University Hospital.

He had been ill for several months with heart disease.

Dr. Kovitz and his wife Dorothy established a visiting professorship in their name at Stanford University School of Medicine in 1969, to bring outstanding lecturers in both surgery and medicine to the school.

A native of Baltimore, Maryland (he was born in 1904), Dr. Kovitz received the bachelor of arts degree from the University of Missouri in 1924, and the medical doctorate from the Washington University School of Medicine in St. Louis in 1929.

He entered general practice in 1932 in Kansas City, Missouri, later specializing in general and industrial surgery.

In 1954, he was made a Fellow of the Industrial Medical Association.

His industrial affiliations in Kansas City included the Hotel Muehlebach, Brown-Strauss Corp., Keystone Trailer and Equipment Company, Woolf Brothers, Burd and Fletcher Company, and Harzfeld's, where he served as medical director.

He was also a member of the Masons, Shriners, and DeMolay.

In 1955, Dr. Kovitz moved to Los Altos, where he continued to practice medicine until his retirement in 1963.

He is survived by his wife and two children, Suzi Kovitz Kohan, of Los Altos, and Louis Kovitz, Jr., of Santa Barbara.

Memorial services will be held Thursday, July 26, at 2:00 p.m., at Roller and Hapgood and Tinney funeral home, 980 Middlefield Rd., Palo Alto.

A new technique developed in Switzerland to open blocked arteries is being used by doctors at Stanford University to enlarge narrowed arteries in legs of patients with peripheral vascular disease.

Popularly known as "balloon dilatation," the procedure involves the insertion of a tube, or catheter, in an artery in the patient's groin.

A special plastic balloon is moved through the catheter to the site of the obstruction and then inflated, compressing the fatty deposits to the artery walls and reopening the vessel to normal blood flow.

According to Dr. Lewis Wexler, associate professor of radiology and chief of the cardiovascular radiology service at Stanford, there is definite promise in the new procedure which, so far, has been used on about a dozen patients, all treated successfully.

Follow-up after nine months shows that the patients' arteries are still wide open, Wexler adds.

Peripheral vascular disease is one result of atherosclerosis, the buildup of fatty deposits in the arteries.

The same type of deposit causes blockages in arteries feeding vital organs such as the heart and kidneys. Heart attack or angina may be the result, or in the case of kidneys, hypertension may follow.

The balloon catheter is currently being evaluated as treatment for these conditions in Europe and in the United States.

In peripheral vascular disease, the blocked arteries feed body extremities, such as the legs, and severe pain on exercise is one result. In more serious cases, gangrene in the toes may set in and amputation of toes or legs may be required.

The condition arises most often in older individuals but others, such as diabetics, are also at risk.

Traditional treatment has been surgical grafting of a new blood vessel, either the patient's own vein or one made of woven dacron, around the blocked portion of the artery. In some cases, the fatty deposits can be removed directly.

However, this is major surgery, notes Wexler, requiring hospitalization for up to a week. Balloon dilatation can be accomplished without general anesthesia and with only one day's hospitalization following the procedure, he says.

"It's important to remember that atherosclerotic disease is progressive and requires continual monitoring and treatment," notes Wexler. "Therefore, any time we can treat the condition with minimal intervention it is advantageous for the patient."

Not everyone with peripheral vascular disease should receive the treatment, Wexler cautions. It works best when large vessels are blocked. Also, if the obstruction is so severe that the balloon cannot penetrate, the procedure can't be used.

"A combination of surgery and balloon dilatation may be beneficial in many cases," he adds.

Dr. Diana Guthaner, assistant professor of radiology, has also performed the procedure on patients at the Veterans Administration Medical Center in Palo Alto.

STANFORD—

Senate Bill 1113, which clarifies California Law regarding the corporate practice of medicine, passed the State Assembly Thursday, July 19, by a 72 to 2 vote.

It will become law in 12 working days unless first vetoed by Governor Jerry Brown.

The bill, sponsored by Senator Barry Keene (D-San Rafael), removes the ambiguity in present law on whether faculty physicians employed in medical schools in California can charge professional fees when they treat patients.

Last Monday, July 9, the Assembly Committee on Health voted nine to zero for passage of the bill with one amendment, that a medical school may bill for services only if the faculty physician who provided the services approves of the charge.

The amended bill was brought to the Assembly floor yesterday by Health Committee chairman Art Torres (D-Los Angeles) who, with Robert Naylor (R-San Mateo), spoke in favor of passage.

After the Assembly vote, Keene brought the amendment to the Senate, and obtained concurrence by a vote of 28 to zero.

The bill had stimulated a vigorous debate during the past months.

Among its most outspoken opponents were Dr. Robert Weinmann, president of Local 7402 of the Union of American Physicians, and Dr. Eugene Dong, a Stanford associate professor of cardiovascular surgery.

Weinmann and Dong maintained that employment of salaried physicians by universities constitutes corporate practice of medicine, which is prohibited in California, and has led to "double billing" and "ghost surgery."

Supporters of the bill, which included Stanford University President Richard W. Lyman, and representatives of the University of California and University of Southern California, argued that preventing the collection of professional fees by salaried faculty physicians would have no beneficial effect.

"The one thing that would be accomplished if the critics had their way would be the outlawing of this method of organizing the clinical activities of medical school faculties," Lyman said at the July 9 hearing of the Assembly Health Committee.

"That is the only thing that would be accomplished—not cost control, not quality control, not an end to abuses which, to the extent that they exist at all, are in any case illegal," he said.

In addition to Lyman, Dr. Lawrence G. Crowley, acting vice-president and dean of the Medical School, and Dr. Irving Schulman, chairman of the department of pediatrics, submitted testimony at the hearing.

They were joined later in the week by the other chairman of the School's clinical departments in calling for the passage of the bill.

STANFORD—

A bill which repeals some controversial requirements for the teaching of human sexuality in California medical schools has been signed into law by Governor Jerry Brown.

The new legislation still requires that physicians in California receive adequate instruction in human sexuality. But medical school faculties determine what, how and who should teach, as they do in all other areas of medical knowledge.

Senate bill 40 was introduced last year by State Senator John Foran (D-San Francisco). It repeals much of AB 4179, which was sponsored by Assemblyman John Vasconcellos and signed into law in 1976.

That law added human sexuality to the list of subjects that physicians must be taught. For the first time it also required the state division of licensing to determine the length and content of instruction. This was a sharp departure from the practice of faculty determining the length and content of courses, and it brought strong opposition from all medical schools in the state.

Former dean of Stanford Medical School, Dr. Clayton Rich, vigorously protested against the law in 1976, calling it a threat to medical curriculum.

Opposition to the law was also voiced by editorials in several California newspapers, including the *Palo Alto Times* (now *Peninsula Times Tribune*), the *San Jose Mercury*, the *San Francisco Chronicle*, and the *Los Angeles Times*.

"Repeal of the human sexuality requirements owes much to the efforts of Dr. Rich, and other medical schools, as well as the newspapers, for bringing the issue to the public and legislature's attention," said Robert Rosenzweig, vice-president of public affairs at Stanford University.

The new law was first introduced as Senate bill 1763 by Foran in 1978. Though passed the Senate and reached the floor of the Assembly, it was not considered before the session ended last fall, and Foran reintroduced it as SB 40

STANFORD—

Two grants, totalling $279,000, have been awarded to Stanford University by the National Institute of Aging for studies of physical and chemical changes, and diseases of older persons.

One of the grants, for $179,000, will support studies of the endocrinology of aging, changes in the secretion of hormones and body chemicals which may be related to problems of old age.

The other grant provides $100,000 for three years for the study of an autoimmune reaction in older people which is caused by commonly used drugs.

Autoimmunity refers to an attack by the body's immune defenses against its own tissues.

Both studies will be conducted in cooperation with the Geriatric Research, Education and Clinical Center (GRECC), based at the Palo Alto Veterans Administration Medical Center.

"There is a pressing need to improve the quality of health care provided to the older person," said Dr. Gerald M. Reaven, director of GRECC and the Stanford Medical School's division of gerontology.

For too long have problems such as diabetes, brittle bones, and decreased sexual activity been considered as natural and unavoidable consequences of aging, he said.

Reaven said the grants are part of a comprehensive program in gerontology at Stanford and the VA, designed to improve understanding of the aging process, and the quality of life of older people.

The endocrinology grant will focus on five areas described below:

• Dr. Julian Davidson, associate professor of physiology, will examine the relationship between aging and sexual behavior.

"It may be that low testosterone (hormone) levels in the older male are related to decreased sexual activity," Reaven said. "If this is so, doctors could apply a medical approach to the problem, rather than telling patients, 'You're too old to be playing around.'"

• Dr. David Feldman, assistant professor of medicine, will examine the effect of age on the absorption of calcium by the gut. Low calcium levels in the blood have been suggested as one cause of the increased rate of osteoporosis, or brittle bone disease, among older people.

• Reaven is exploring the link between changes in the breakdown of glucose and insulin which occur during aging, and glucose intolerance, a decline in the ability to transport sugars from the blood into body tissues.

"This intolerance may be responsible for elevated blood levels of fats, which are associated with atherosclerosis," he said.

– more –

• Dr. Herbert Schwartz, professor of pediatrics, will test older people for the presence of a glucose-containing hemoglobin molecule, A1c.

This molecule is elevated in the blood of diabetics, and is thought to reflect control of abnormal metabolic processes which may underlie complications of the disease, including blindness, kidney failure and other vascular problems.

The presence of A1c in the blood of older people may provide clues to the increased incidence of degenerative disease in that age group, Reaven said.

• Dr. Raymond Hintz, associate professor of pediatrics, will test the response of tissues from patients of various ages to somatomedin, a hormone involved in the stimulation of growth. The studies are aimed at answering basic questions of why and how cellular aging occurs, Reaven said.

The second NIA grant is directed by Dr. Thomas Okarma, staff physician in the division of gerontology.

According to Okarma, 10 to 15 percent of patients given certain drugs to treat conditions such as high blood pressure or abnormal heart rhythms develop symptoms or blood test abnormalities similar to a form of arthritis called systemic lupus erythematosus (SLE).

SLE is characterized chemically by the presence of complexes of immune molecules in the blood, and clinically by skin rashes, joint swelling, and inflammation of internal organs. It is thought to be an autoimmune disease.

Unlike SLE, the drug-caused symptoms occur more frequently among older people, and usually disappear when the drugs are withdrawn, Okarma said.

What is important about the drug reaction is that it provides a model in humans of the way autoimmune diseases may develop, he said.

In addition, "study of this phenomenon in older people may provide insight into the molecular biology of cellular aging, and potentially may provide clues to understanding the uncontrolled cell growth which characterizes tumors," he said.

STANFORD—

A major research program on nerve disease has been established jointly by Stanford University and the Palo Alto Veterans Administration Medical Center (VAMC).

The program is supported by grants from the National Institutes of Health (NIH), the Veterans Administration and the Kroc Foundation.

It includes the first axonal disease laboratory in the U.S.

Axons are the nerve fibers which transmit messages within the nervous system. They are involved in a wide range of diseases, including multiple sclerosis, leprosy, and alcoholism.

The driving force behind the new program is its soft-spoken, enthusiastic director, Dr. Stephen G. Waxman.

At the age of 33, Waxman is an international authority on diseases of nerve fibers. His achievements include authoring more than 85 scientific papers, membership in several societies, including the American Association for the Advancement of Science, and the Annual Trygve Tuve Memorial Award for outstanding contributions in biomedical sciences from the NIH.

The product of Harvard College and Albert Einstein College of Medicine, where he received both his M.D. and Ph.D., Waxman taught at Harvard and the Massachusetts Institute of Technology before coming to Stanford in 1978.

He currently is professor of neurology at Stanford Medical School, and chief of the Neurological Unit at the VAMC.

Waxman conducts visitors through his laboratory at the VAMC with the pride of a new father in a maternity ward.

Though not yet complete, the lab eventually will house an electron microscope, banks of computers, a dark room, and working quarters for Waxman's colleague, Dr. Jeffrey D. Kocsis, five research associates, and support personnel.

"This lab is bringing together scientists from a variety of disciplines—neurologists, morphologists, biophysicists, engineers, biochemists, physiologists—to look at diseases of the axon," Waxman says.

"We'll be examining the molecular structure of the nerve cell membrane with electron microscopy and freeze-fracture methods, recording electrical signals from single nerve fibers, and simulating behavior of normal and diseased nerve fibers with a computer—all to better understand disease."

The root of many nerve diseases and injuries is destruction of the insulation of nerve cells, called the myelin. When the insulation is destroyed, electrical conduction can be completely disrupted, causing muscle weakness, pain, paralysis, and other problems.

- more -

"Myelin is destroyed in a number of disorders of nerves peripheral to, or outside of the brain and spine," Waxman says. "These include diabetes, which afflicts over one million people in the U.S., and alcoholism."

A common disease seen primarily in underdeveloped countries is leprosy. "The disease affects nerves running to the limbs and face," he says, "and the medical toll here is tremendous."

Loss of myelin also occurs in diseases which strike the central nervous system, the brain and spinal cord. The most familiar example is multiple sclerosis (MS), which may afflict as many as 100,000 people in the U.S., most of them in their 20s to 40s.

"In the case of MS, a degree of spontaneous recovery often occurs, yet we know little about the physiological and biochemical mechanisms underlying this recovery," Waxman says.

There are indications that MS may be related to an inborn error in the body's immunologic machinery, such that the body begins to attack itself. Possible exposure to a virus has also been suggested as a cause.

Yet, so far, no specific treatment has been found for MS. Waxman and his group have concentrated on studying the molecular architecture of the nerve fiber membrane, and the mechanisms of spontaneous recovery, in the hope that they will find therapies for stimulating recovery from diseases such as MS.

But, Waxman adds quickly, "We cannot promise a cure for axonal diseases in one year, or two years, or even five years. Each month, however, we come a bit closer to understanding the disease processes.

"In the long run, cures for many axonal diseases will be found."

One of the most intriguing projects underway at the axonal disease lab is the study of the black ghost knife fish, *Sternarchus*.

This South American fresh water fish has the unusual ability for regrowing its spinal cord after it has been completely severed.

Spinal cord injuries are one of the most devastating of any nervous disorder, often resulting in irreversible paralysis.

For some reason, nerves of the spine and brain in most animals, including humans, are less plastic than those in the limbs. They do not regenerate well. Waxman says the difference may have something to do with the way central nerve cells produce their insulation.

The myelin covering each peripheral nerve fiber is produced by a single Schwann cell, in close proximity to the nerve, whereas central nerve myelin is produced by another type of cell, called an oligodendrocyte, which may supply as many as 50 different nerve fibers.

"The connections are more tenuous in the central nervous system," says Waxman, "and possibly are disrupted more easily."

Waxman believes that by unravelling the mysterious regenerative properties of the black ghost knife fish and related species, he and his associates may be closer to understanding what determines function of central nerve fibers, and how they may be encouraged to regrow after an injury.

FOR IMMEDIATE RELEASE

STANFORD—

The California Assembly Committee on Health voted nine to zero for passage of Senate Bill 1113 at a hearing Monday, July 9, which included testimony by Stanford University President Richard W. Lyman.

The bill, sponsored by State Senator Barry Keene (D-San Rafael), removes the ambiguity in present law on whether faculty physicians employed in medical schools in the state can charge professional fees when they treat patients.

The bill now goes to the floor of the assembly, according to University director of government relations Larry Horton.

However, the bill took one amendment during the hearing, that a medical school may bill for services only if the faculty physician who provided the services approves of the charge.

The bill, which was passed last May by the Senate, also will be returned to that body for approval of the amendment, Horton said.

During the 90 minute hearing, testimony in support of the bill was given by Lyman, Dr. Lawrence G. Crowley, acting vice-president and dean of the Medical School, and Dr. Irving Schulman, professor and chairman of the department of pediatrics.

Also present and supporting the bill were Dr. Alan Mathies, dean of the University of Southern California School of Medicine, and Steve Arditti, legislative representative for the University of California.

Opponents of the bill presenting testimony at the hearing included Dr. Robert Weinmann, president of Local 7402 of the Union of American Physicians, and Dr. Eugene Dong, a Stanford associate professor of cardiovascular surgery.

Weinmann and Dong have maintained that employment of salaried physicians by universities is illegal, and Weinmann also has alleged the practice led to "ghost surgery," "double-billing," and "double-dipping" into public programs such as Medicare and Medi-Cal.

In response, Lyman said at the hearing that while medical schools are far from perfect, "they are not peopled with money-grubbing and inhuman villains, either."

In testimony prepared for the committee, Schulman stated that professional fees charged by faculty physicians are provided to the Medical School "as a contribution to the support of the academic effort (teaching, research, and patient care) as a whole.

"I believe that (this practice) has resulted in very high quality medical education for the physicians of the future, and in a system of exemplary medical care for the patients we are privileged to serve," he said.

TWO RELEASES

STANFORD—

Two postdoctoral researchers in the department of pathology at Stanford University School of Medicine will receive two-year fellowships from the Leukemia Society of America to support basic research on causes and prevention of leukemia.

Dr. Rolf H. Joho, research assistant, has been awarded a $31,000 grant and Douglas P. Tapper, currently completing his graduate education at Harvard University, will receive a $25,000 fellowship when he arrives in December.

Leukemia is a malignant disease striking about 55,000 Americans each year. Among diseases leukemia is the number one killer of children, according to the society.

Joho will examine the organization and expression of immunoglobulin genes during white blood cell formation.

Understanding the normal process of white blood cell maturation may provide a basis for preventing the abnormal process that occurs in leukemic cells, he suggests.

Tapper will study the replication of genetic material (DNA) found in mitochondria, the energy producing bodies of cells.

Abnormal mitochondrial DNA is associated with granulocytic leukemia in humans, he explains.

Joho and Tapper are among 132 scientists supported by the Leukemia Society at 60 institutions in the U.S. and abroad. Annual funding for the grants, according to the society, is over $2 million.

The Leukemia Society also supports patient aid programs and education programs through local chapters across the U.S..

—30—

STANFORD—

Vansen R. Wong, a recent Stanford graduate, has been awarded a $1,500 three-month student research fellowship from the American Liver Foundation.

Wong will work this summer with Dr. Allen D. Cooper, assistant professor of medicine in gastroenterology at Stanford University Medical Center.

The award was made on the basis of a national competition, according to the foundation, and Wong, a native of Piedmont, was one of eight students selected for a fellowship.

He will study aspects of liver cancer in rats.

Normally, the liver responds to a high cholesterol diet by decreasing synthesis of cholesterol, Wong explains. But in rats, cancerous liver tissue does not display this type of feedback inhibition.

Cholesterol is carried in particles called lipoproteins. Wong and Cooper think the cancer cells may have altered lipoprotein receptors. This could be useful for diagnostic or therapeutic purposes, they add, providing a way to distinguish the cancer tissue from normal tissue.

The American Liver Foundation is a national voluntary health agency, concerned with the understanding, prevention and cure of liver diseases.

This is the first year of a new research training program for young investigators, the foundation said.

STANFORD—

Stanford University President Richard W. Lyman Monday urged passage of Senate Bill 1113 because it would enable medical schools in California to proceed with their work in the interests of the public, "free of the wearisome, repetitive and baseless round of attacks" made by some critics.

Lyman expressed his views in testimony prepared for delivery before the California Assembly Committee on Health in Sacramento.

The bill, sponsored by State Sen. Barry Keene (D-San Rafael), would remove the ambiguity in present law on whether faculty physicians employed by medical schools in the state can charge professional fees when they treat patients.

Two critics of the bill, Dr. Robert Weinmann, president of Local 7402 of the Union of American Physicians, and Dr. Eugene Dong, a Stanford associate professor of cardiovascular surgery, have maintained that employment of salaried physicians by the universities constitutes corporate practice of medicine explicitly prohibited in California.

Moreover, Dr. Weinmann has alleged that employment of salaried physicians by the schools has led to "ghost surgery," "double-billing," and "double-dipping" into public programs such as Medi-Cal and Medicare.

"Our universities, and the medical schools within them, are far from perfect," Lyman said. "But they are not peopled with money-grubbing and inhumane villains, either."

"The purpose of the corporate practice of medicine law," Lyman said, "was to prevent commercial exploitation of the medical profession for profit.

"It is not and never was to prevent the employment of faculty physicians who draw salaries from their universities and spend a portion of their time providing patient care, in return for fees that then can revert to the employing university.

"The one thing that would be accomplished if the critics had their way," Lyman said, "would be the outlawing of this method of organizing the clinical activities of medical school faculties.

- more -

"That is the only thing that would be accomplished--not cost control, not quality control, not an end to abuses which, to the extent that they exist at all, are in any case illegal."

The effect of lack of legislation in this matter, Lyman said, would be that the so-called "full-time" system in which faculty doctors draw salaries instead of being compensated directly in professional fees, would be cut off.

"If that should happen," he said, "it will not be the end of the world. But neither will it be advantageous for the citizens of California."

A medical school faculty, he explained, comes to academic life because of interest in teaching and research, in addition to clinical care for patients.

"Faculty members, were they mainly concerned with making money, would never have taken up academic life in the first place," Lyman said. "They could make a lot of money outside, in private practice, charging their own fees and, of course, pocketing them.

"Yet somehow their decision to enter academic medicine is being converted, by the opponents of S.B. 1113 into a kind of illegitimacy.

"It is to be made illegitimate for them to practice their profession under an agreement that to the extent that they bill for their services (and we at Stanford do not determine that extent), the fees paid shall go back to the School that pays their salaries."

Lyman said if S.B. 1113 does not pass, universities will have to contract for clinical care with new corporations consisting of their faculties.

"Those corporations will do their own billing," he said. "I do not believe that any serious observer will conclude that such a change in how faculty members are compensated would even begin to address, let alone remove, the forest of evils that the critics of this bill have so ingeniously managed to summon out of their own fevered imaginations."

STANFORD—

Stanford University Hospital faces a $2.4 million cut in its annual revenue, as a result of new government regulations which set lower limits on reimbursement for hospital services to Medicare and Medi-Cal patients.

For the same services provided currently to patients for $191 per day, the government will now reimburse Stanford and other similar sized California hospitals $168 per day beginning next year, said Dr. Peter J. Levin, executive director of the hospital.

Medicare and Medi-Cal patients make up between 47 and 49 percent of the hospital patient population.

"Considering inflation this past year, the impact of the decrease is even greater," Levin said.

In addition, "these new regulations make it impossible for hospitals to plan rationally, based on their expectations of reimbursement for coming years," he said.

According to the California Hospital Association, nearly 50 percent of California hospitals will be adversely affected by the regulations.

Last week, 36 California congressmen, in a letter to Joseph Califano, head of the Department of Health, Education and Welfare (HEW), protested the "inequitable bias" which the regulations cause against California and certain teaching hospitals.

The letter stated that the per day limits do not sufficiently reimburse California hospitals, which have "substantially shorter" hospital stays than the national average.

Shorter stays indicate a more intensive level of care, and thus a higher cost per day, but lower overall hospital and Medicare costs.

In addition, the congressmen argued that the regulations made inadequate provision for the costs associated with teaching and delivering intensive care to large numbers of patients in teaching hospitals.

The congressmen recommended changes in the limits to recognize the savings from shorter days and the additional costs borne by teaching hospitals.

Unless the requested relief is provided, concluded the congressmen, "hospitals have no alternative but to pass unmet costs on to the non-government payers."

- more -

Beginning September 1, hospital administrators are faced with three alternatives:

• raising prices charged to non-Medicare patients to make up for the loss in revenue (the government already pays 18 percent less than charges to non-government patients),

• accepting the revenue loss, which may mean badly needed equipment and new construction will not be financed, or

• cutting expenses further, thus compromising the quality of patient services.

"The government is forcing us into an untenable position," Levin said.

Substantial amounts of money for capital investment are needed over the next few years for routine and preventive maintenance, and for up-grading the 20-year-old building to meet current government codes, he said.

Yet, according to hospital administrator Gary Mecklenburg, the hospital already has cut the annual rate of increase of hospital costs to nine percent, below both the national average (14 percent) and the President's guidelines (9.7 percent).

To hold down costs, hospital administrators and department heads have been asked to streamline their operations and carefully review their budget requests for the coming year.

Mecklenburg said the administration is considering several options to meet the contingency of lost revenue, prior to submitting the 1979-80 budget to the Hospital Board of Directors for approval in August.

"And we are fighting the regulations," he said.

Stanford officials so far have not received a response to the letter sent to HEW last week, although Levin said they are hopeful the regulations will be changed.

In the meantime, the hospital has an alternative to file for an exception with HEW's Health Care Financing Administration, to permit it to exceed the limits of reimbursement.

However, said Levin, "according to past experience, exceptions have been very difficult to obtain."

STANFORD—

Clinical chairmen in the Stanford University School of Medicine have endorsed 8 to 2 a bill now before the State Assembly intended to clarify how faculty doctors in the state's public and private medical schools charge professional fees.

The clinical subcommittee of the School has voted to support SB 1113, scheduled for hearings beginning July 9 by the Assembly Health Committee, and passed by the State Senate in May under the sponsorship of State Sen. Barry Keene (D-San Rafael).

The clinical subcommittee, made up of the chairmen of the School's 11 clinical departments, said it supported the bill with the understanding that its passage "would remove the ambiguity in the present law."

The law in question is Section 2008 of the Business and Professions Code which stipulates that medical schools in California may employ salaried faculty physicians provided that they see patients free of charge.

The passage of SB 1113, the subcommittee said, "would enable the faculty of Stanford University Medical School to continue its long standing practice (20 years) of submitting bills for professional services they provide."

The clinical subcommittee said that if SB 1113 became law, they had been assured that the University had no intention of changing its policy regarding who has the right to charge professional fees for the clinical services provided by the faculty.

Last week, writing to Senator Keene in opposition of SB 1113, Dr. Norman E. Shumway, professor and chairman of the cardiovascular surgery department, said the new law "interferes substantially with, if it is not totally obliterative of, the doctor-patient relationship."

"The very last or bottom line of that relationship," wrote Shumway, "is the time honored or traditional bill. To assign this prerogative to the administrative agent of financially stressed institutions is to guarantee invariably the rendering of a bill at the highest level."

In a letter to Acting Vice President and Dean Lawrence G. Crowley, Stanford University President Richard W. Lyman wrote:

"This is to reaffirm, as strongly as I can, that the University has absolutely no intention of changing the current policy.

"The current policy is that it is within the sole discretion of the faculty physician to determine if a bill for his or her professional services should be submitted to a patient, and how much the charge, if any, should be.

"This has been the policy of the University since the current system was established in 1959, and the University fully intends to continue this policy in the future."

SB 1113 is backed by Stanford, the University of Southern California, and the UC system of medical schools.

STANFORD—

Anesthetics will soon be tested in the breathing mixtures of deep sea divers to counteract effects of high pressure nervous syndrome, a disorder often experienced by divers at great depths, according to a Stanford University researcher.

Dr. Joan J. Kendig, associate professor of biology in anesthesia, says it has been known for some time that high pressure and anesthetic action are antagonistic.

This antagonism may be a valuable tool to help scientists discover the cellular basis of how anesthetics work, she suggests. It also has practical applications for deep sea diving.

Normally, divers supplement their breathing mixture with 10 percent nitrogen to minimize effects of high pressure nervous syndrome.

But nitrogen is soluble in blood and can cause another diving hazard known as the bends, or formation of nitrogen bubbles in the blood. Anesthetics are less soluble, eliminating this danger, she says.

Kendig and her colleagues are currently determining precise concentrations of anesthetics required to replace the nitrogen.

Deep sea divers then test the anesthetics during actual dives in special pressure chambers at various institutions across the country (including Duke University), she says.

In addition, there is a multinational effort involving France, Britain and the United States, spurred on by commercial interests with operations in deep water such as oil rigs in the North Sea, she adds.

Kendig explains that studies of cell membranes have revealed that the lipid (fat) component of the membrane acts like a fluid.

Proteins embedded in this lipid layer carry out important cell membrane functions such as controlling passage of molecules in and out of the cell, she adds.

In nerve cells, the passage of charged particles through the membrane is responsible for nerve cell firing.

Proteins in the membrane require a precise degree of fluidity in order to function properly, she says.

Anesthetics seem to increase the fluidity of the membrane while high pressure rigidifies the structure, according to studies carried out by Kendig and her colleagues.

Still to be discovered is the exact way anesthetics alter the membrane fluidity and how this disturbs the nerve cell function, she explains.

Kendig's research also focuses on the important clinical finding that local anesthetics applied intravenously in small concentrations will stop arrhythmic disturbances in the heart.

"The more rapidly a nerve is carrying impulses, the deeper the local anesthetic block appears to be," she says.

"Local anesthetics may actually prevent cardiac muscle from generating impulses at higher than normal frequency," she adds.

Kendig presented recent results of her research at the Symposium on Molecular Mechanisms of. Anesthesia held in Seattle last month.

Her research is supported by the National Institutes of Health and by the U.S. Navy.

STANFORD—

If you want to help medical science in its fight against kidney disease, here is your chance:

Stanford Medical School researchers are seeking adult volunteers for a study of a new technique for measuring kidney function.

The technique, developed at Stanford, measures the flow of different sugars through the kidney's filters, and their appearance in the blood and urine.

"This new test may be important in understanding kidney diseases, as well as improving their early diagnosis and treatment," said Dr. Bryan D. Myers, assistant professor of medicine.

Myers is directing the study under a grant from the National Institutes of Health with Dr. Stefan A. Unterhalter, a fellow in the division of nephrology.

Volunteers are needed to help establish the normal range of sugar filtration by the kidney, Myers said.

Kidney problems can accompany several diseases, including diabetes and some forms of cancer. In addition, kidney failure can follow open-heart surgery.

The most common and earliest sign of disease is the appearance of protein in the urine, he said. By measuring the filtration of sugar "markers" similar in size to proteins, physicians may be able to detect disease earlier, and evaluate therapy better than is now possible.

In addition, Myers said the test may provide clues to the defect in the kidney filter which allows proteins to seep through.

The study will be conducted on an outpatient basis. Volunteers will be given two polysaccharides, composed of the sugars fructose and glucose, and samples of their blood and urine will be collected during a three hour period.

Volunteers will be paid.

Persons wishing to participate in the study should contact Dr. Unterhalter, at the Stanford Hemodialysis Center, 497-7256.

STANFORD—

Scoliosis, an abnormal curvature of the spine, is the most common handicap among children, according to a Stanford University researcher who recently launched a long-term study to discover if abnormalities in the body's posture control system cause one form of the disease.

Two out of 100 children are afflicted, according to Dr. Eugene Bleck, professor of clinical surgery at Stanford and chief of pediatric orthopedics at Children's Hospital at Stanford.

If left untreated scoliosis may progress, causing disfigurement and other problems such as breathing difficulties and impaired circulation.

There are many types of scoliosis, explains Bleck, and some are associated with other diseases. But for a large number of patients with scoliosis, there is no clear cause for the condition. This type is known as idiopathic scoliosis.

Current treatment for idiopathic scoliosis involves mechanical support with various types of braces worn for a period of years, from the time the curvature is discovered until the patient's skeleton matures.

But not all curves are severe enough to warrant treatment, Bleck says, and one problem he wants to solve is how to identify those cases likely to "progress" or worsen.

In a recent study of children with scoliosis, it was shown that about half had progressively worsening curvature while the other half spontaneously recovered, he notes.

Although mechanical braces do help control severe cases, many children may be needlessly exposed to years of unnecessary bracing since progressive cases cannot currently be identified.

On the basis of pilot studies he has completed, Bleck suspects that idiopathic scoliosis could be a neurological disorder involving an abnormality of the body's posture control system.

To test this idea, he plans to measure balance reflexes of children with scoliosis and those of a group of normal children. During follow-up studies over several years, he will record patients' spinal curvature and balance reflexes to detect a possible correlation between neurological posture control and scoliosis.

A neurological abnormality seems plausible, since it is known that idiopathic scoliosis is neither a muscular nor a skeletal disorder, Bleck explains.

Bleck and his colleagues are also testing two new methods of treatment of scoliosis. One uses direct electrical stimulation of the spine muscles during sleep. The other is an augmented feedback plastic brace that reminds the child to shift the trunk at regular intervals during the day.

If the basis of idiopathic scoliosis is abnormal neuromuscular control, then this new brace could be particularly effective, he suggests.

STANFORD—

Researchers at Stanford University have begun a study of the long-term effects of relaxation training on high blood pressure.

The four-year study is supported this year with a $100,000 grant from the National Heart, Lung and Blood Institute.

According to study director Dr. Stewart Agras, professor of psychiatry at the Medical School, several reports have shown that relaxation training can cause reductions in blood pressure.

The decreased blood pressure may last as long as one year without close follow-up training, he said.

Relaxation training is particularly important for 40 percent of hypertensive patients, whose blood pressure is not completely controlled by medication alone, Agras said.

However, doctors do not know how long the technique remains effective once it has been learned, or whether a few minutes of relaxation in the morning can keep blood pressure down for the rest of the day.

To answer these questions, Agras and his colleagues will follow 260 persons with essential hypertension requiring medication who have been recruited from local industries.

All of the subjects will remain on their medication, but, in addition, half of them will receive training in relaxation techniques, such as sequential muscle tensing and relaxing.

These subjects will be instructed to practice the techniques at home every day, and whenever they feel tense.

An automatic monitor worn by some of the subjects during certain phases of the study will provide a record of blood pressure throughout the day.

Further training will be given every two months to some of the subjects who were taught the techniques initially, to make sure they are consistently practicing relaxation.

Agras said the study is a first step in determining the role of relaxation training in the management of essential hypertension, a disorder which afflicts an estimated 23 million Americans.

STANFORD—

University Hospital room rates will increase an average of $20 in the new fiscal year starting September 1.

Medical, surgical, and gynecology room rates, which are charged to most hospitalized patients, will increase an average of 11.6 percent from those set a year ago.

The new rates, according to Dr. Peter J. Levin, executive director of the hospital, reflect increased wages and operating costs, and an anticipated reduction in reimbursement from the government for care given to Medicare and Medi-Cal patients.

"They also reflect our ability to hold down costs in a time of rapid inflation," Levin said.

For example, he said, hospital expenses will rise by 9.3 percent this year, well within the voluntary guidelines for cost containment, and "much better" than the industry average, 13 percent.

The new room rates were approved by the University after the Board of Hospital Directors reviewed the annual budget on August 21, recommending rates for the fiscal year 1979-1980.

These rates may be increased later this year, Levin said, unless new government regulations reducing reimbursement for hospital services to Medicare and Medi-Cal patients are softened.

The current schedule of limitations, set this summer by the Health Care Financing Administration, result in a reduction of about $2 million in the hospital's annual revenue.

Officials of the California Hospital Association, the Association of American Medical Colleges, and Stanford are trying to get the government to ease the regulations, Levin said, and they have received the support of the California congressional delegation.

"At this time, however, we cannot be certain that the regulations will be eased," he said.

Beginning September 1, the new room rates will be $178 per day for ward accommodations, $192 for a semiprivate room, and $214 for a private room, up an average of $20 from last year.

Medical, surgical and gynecology services of house staff physicians are offered to patients for $16 more than the above rates.

The level of rate increases will be an average of 12.8 percent for some specialized units, including the intensive and coronary care units and the nurseries.

Rates for psychiatry, obstetrics, and pediatrics will increase 11.5 percent.

Rates for X-ray, laboratory, and other ancillary services will be increased an average 11.4 percent.

In addition to meeting increased operating costs, and partially recovering the loss in government reimbursement, the increase in room rates is necessary to provide money for improving facilities and meeting code requirements, Levin said.

Current projects include renovation of the neonatal intensive care unit, completion of the "Phase 1" building (in the hospital's North wing), and planning long-term construction needs.

Patient revenues make up 99 percent of the hospital's funds, Levin said. The hospital has no tax support or endowment income.

Dr. Wilbur E. Mattison, a Menlo Park physician since 1958, has been elected president of the medical staff at Stanford University Hospital.

Mattison succeeds Palo Alto heart surgeon Dr. Thomas J. Fogarty, and will take office on September 1 for a two-year term. He was recently elected by mail ballot of the active medical staff, comprising about 900 faculty and community physicians, according to Dr. James F. Silverman, chief of staff.

As president, Mattison will serve as representative of the medical staff to the Medical Board, to the chief executive officer and to the hospital's Board of Directors.

"My primary goal is to assist in the activation of the medical staff and to improve communication among members," he said. "A well organized medical staff is vital to the smooth operation of any hospital."

Mattison received his M.D. degree from the Johns Hopkins University Medical School in 1952 and served his internship and residency there until 1958, when he set up medical practice in Menlo Park at the Menlo Medical Clinic.

He has been a staff member at Stanford University Hospital since 1958, and is clinical associate professor of medicine at Stanford University School of Medicine. He also has served on numerous hospital committees.

STANFORD—

Researchers at Stanford University Medical School and the National Aeronautics and Space Administration (NASA) are looking for 12 able-bodied men aged 45-55 to help them prepare for the first launching of the space shuttle.

The volunteers simply will be put to bed at Stanford University Hospital, while the researchers study changes in their hearts, kidneys, circulatory and hormonal systems.

Long-term bedrest simulates the effects of weightlessness, which occurs during space flight, explained Dr. Danielle Goldwater, scientist at the NASA Ames Research Center in Mountain View, and member of the clinical faculty at Stanford Medical School.

Blood volume decreases, and the heart and blood vessels may lose tone during weightlessness, leading to drops in blood pressure and exercise capacity on return to the Earth's gravity. In addition, drugs may affect the body differently when it is weightless or horizontal for long periods, Goldwater said.

"In the near future, NASA plans to open up space flight to people middle aged and older," she said. (The first space shuttle launch is expected in the summer of 1980).

Middle-aged people are susceptible to heart disease, high blood pressure, mild diabetes, and other problems, Goldwater said, and therefore it is important to know how this age group responds to simulated weightlessness, and how to reverse the deconditioning effects.

In addition to its usefulness to the space program, Goldwater said the study may shed some light on the effects of long-term bedrest here on Earth, as during an illness.

For instance, she said, heart attack patients usually are treated with eight to 10 days of bedrest. But that treatment may add to the disabling effects of the heart attack, by making patients even weaker.

The Stanford study is an outgrowth of five years of investigations into weightlessness by Dr. Harold Sandler, director of the Ames' Biomedical Research Division.

It is supported by grants from NASA and the National Institutes of Health.

- more -

Other Stanford investigators include Drs. Donald C. Harrison, Richard L. Popp, and Robert E. Kates of the division of cardiology, Robert F. DeBusk, director of the Cardiac Rehabilitation Program, John A. Luetscher, Jr., of the division of endocrinology, and Michael L. Goris of the nuclear medicine division.

The study is scheduled to begin September 4, and will run through November, Goldwater said.

Two volunteers at a time will be admitted to the Hospital's Clinical Research Center for 14 days. They will stay active for the first four days, to establish a baseline of their cardiovascular and hormonal functions, and the remaining 10 days they will be confined to bed.

Blood tests will monitor changes in the metabolism of the men, and in their response to certain drugs.

At the end of the 10 days, a special device which exerts a negative pressure on the lower body will be used to test heart and circulatory functions. In addition, the ability of the heart and muscles to use oxygen efficiently will be tested as subjects pedal a stationary bicycle.

Once released from the hospital, the volunteers will resume normal activities. Half of them, however, will exercise an additional 30 minutes each day, to determine if extra activity helps them recover more quickly from their time spent in bed.

Healthy, middle-aged males interested in participating in the study should call Mr. Bob Peterson, of Management Systems Associates in San Jose, at (408) 286-0460.

STANFORD—

Dr. Samuel C. Ballon, well known authority on reproductive cancers in women, has been appointed associate professor of gynecology and obstetrics at Stanford University School of Medicine.

Ballon also will head the newly-established section of gynecologic oncology, which will provide comprehensive care and study of cancers of the reproductive tract, including the ovary, vulva, vagina, cervix and endometrium (uterus).

The appointment was announced recently by Dr. Lawrence G. Crowley, vice president and acting dean of the Medical School.

"Dr. Ballon is an extraordinarily well-trained man," said Dr. Joseph Portnuff, clinical professor of gynecology and obstetrics, who taught Ballon as a resident and who encouraged him to take the new job. "He is an outstanding addition to the Department."

A native of Montreal, Canada, Ballon, 34, was educated at that city's McGill University, receiving his bachelor of arts degree with honors in 1965, and his M.D. in 1969.

He served as resident and chief resident in gynecology and obstetrics at Stanford from 1971 to 1974, and was a fellow in gynecologic oncology at the Memorial Sloan-Kettering Cancer Center in New York from 1974 to 1976.

He then moved to the University of California at Los Angeles, where he was associate professor of obstetrics and gynecology, and associate director of the division of gynecologic oncology until leaving for Stanford this year.

Ballon is a member of several professional societies, including the New York Academy of Sciences, the American Radium Society, and the Society of Gynecologic Oncologists. He is a fellow of the American College of Surgeons and the American College of Obstretricians and Gynecologists.

He was awarded the Galloway Fellowship by the Memorial Hospital for Cancer and Allied Diseases in 1973, and received a certificate of appreciation from the California Division of the American Cancer Society in 1978.

A self described "workaholic," Ballon said he came to Stanford for the challenge of building a top-notch program in gynecologic oncology.

"We can provide an important service to the women of the South Bay Area," he said.

- more -

Specialists in female reproductive cancers can deliver primary care to women whose treatment is often "fragmented," Ballon said, because as gynecologic oncologists they have received training in surgery, radiation therapy, and chemotherapy, as well as gynecology.

Ideally, they can help make the patient a part of her own treatment team, he added, by teaching her about her disease and what to expect from therapy. Patient education will be an important goal of the new program, he said.

Over 100 physicians nationwide have been certified in gynecologic oncology since the field was established by the American Board of Obstetrics and Gynecology in 1972.

Ballon would like to prepare future doctors for the field, by establishing resident and fellowship training programs. Physicians will develop competence in radiation therapy, chemotherapy, immunology and basic research, as they pertain to female reproductive tract tumors, he said, and they will be well grounded in principles of diagnosis, staging and management of the cancers.

At the same time, Ballon plans to develop active research programs to improve cancer diagnosis and treatment.

Ovarian cancer strikes over 17,000 and kills 11,000 women in the United States each year, and survival rates have not improved since 1949. Recently, new drugs such as cis-platinum have been found to be effective in treating ovarian cancer, but the most needed research is in finding a test which can make the diagnosis early, before the cancer has spread to other parts of the body.

Ballon's other research interests include reconstructive surgery of parts of the body damaged by cancer and cancer treatments, chemotherapy, and hyperalimentation, or high nutrient intravenous feeding.

A principal investigator in the national Gynecological Oncology Group, Ballon said he also expects to contribute to the research efforts of the Northern California Cancer Program.

STANFORD—

Governor Jerry Brown recently signed into law a bill which provides permanent funding for the California Infant Medical Dispatch Centers.

Assembly Bill 810, introduced by Assemblyman Leroy Greene (D-Carmichael), provides $207,000 annually for support of two centers, one based at Stanford University and the other at the University of Southern California.

The centers have helped physicians locate intensive care nursery beds for critically ill babies, and have arranged transport of the babies, since they were established on a pilot basis by the State Legislature in 1975.

"I am delighted," said Dr. Alvin Hackel, director of the Northern California Dispatch Center.

"We should be particularly pleased as this program was pioneered at Stanford, and provides an important service to the California perinatal community.

"The support of the National Foundation of the March of Dimes is especially appreciated," Hackel said, "as it guaranteed funding of the Northern California center for two months in the event the bill did not pass."

The Northern California Dispatch Center serves a 200,000 square mile region from the Oregon border to the Tehachipi Mountains. About 120,000 infants are born in the 168 hospitals in the area each year, of which over 2,000 require transport to intensive care or intermediate intensive care nurseries.

There are 250 intensive care beds in 10 hospitals in the region, but at any one time, only five may be available. Prior to the establishment of the Dispatch Centers, Hackel said, doctors spent as long as two and a half hours on the phone just locating an available bed.

"We consider this similar to having a patient in shock lying in an intersection, not receiving the type of care he needs," he said. "We feel this extra time comprises the ultimate outcome of these patients."

Today, the time it takes to locate a bed has been cut to 20 minutes. At Stanford, for instance, dispatchers under the direction of Tricia Robertson and Jennifer Whited call the regional intensive care nurseries for an up-date on bed availability three times a day.

- more -

When a call comes into the center, the dispatchers find the intensive care bed closest to the referring hospital, and coordinate transport by ambulance or airplane.

In 1978, the Dispatch Center arranged nearly 600 transports, some for the distances over 250 miles.

An air-to-ground communications system developed by Dr. Jan Ehrenwerth, associate director of the center, enables physicians to maintain continuous contact with the transport crew during flights.

Hackel said the new funding would allow the program to decrease the time it takes to locate a bed even further through the use of computers.

Plans include installation of automatic bed counters at each intensive care nursery. Eventually, said Hackel, every hospital in the region will have its own computer terminal. Doctors then could call up the latest bed availability information without having to phone the dispatch center, much in the same way that travel agencies can call up seat availability on airlines.

The addition of memory and data processing capabilities to the computer will also enable the center to evaluate the effectiveness of the dispatch program, Hackel said.

The ultimate goal of the program, he said, is to coordinate emergency transport, not only of critically ill infants, but of high risk mothers and adult patients as well.

Already, Stanford transports pregnant women who are at high risk for complications during pregnancy, and adult patients are transported under the Stanford Emergency Transport Service.

At the State level, Senator Barry Keene (D-San Rafael) is sponsoring a bill which would require the Department of Health Services to develop a regional perinatal transport system for both mothers and infants.

The bill, SB 775, passed the Senate on June 20 and is now awaiting action in the Assembly Ways and Means Committee.

STANFORD—

Governor Brown has signed into law Senate Bill 1113, which clarifies the manner in which faculty physicians in medical schools bill their patients.

The bill, sponsored by State Senator Barry Keene (D-San Rafael), was signed Wednesday night, August 1. It had passed the State Assembly by a 72 to 2 vote on July 19. Assemblyman Art Torres (D-Los Angeles) carried the bill on the floor of the Assembly.

"We are extremely pleased by the size of the vote supporting SB1113, and by the Governor's signature," said Robert Rosenzweig, vice-president of public affairs at Stanford University, which had strongly supported the bill.

"It suggests that we succeeded in demonstrating that the way in which we have been operating at Stanford is responsible and consistent with sound medical practice," he said.

"We are glad this issue is behind us," said Dr. Lawrence G. Crowley, acting vice-president and dean of the Medical School. "It has been very time-consuming for all concerned.

"There are many important and positive things to be accomplished at the Medical Center, and resolution of this matter will allow us to devote more of our energies to them," he said.

Passage of SB1113 means that the existing practice at medical schools such as Stanford is considered legal under present law, which prohibits the corporate practice of medicine.

The problem emerged as a public issue because of complaints filed by the Union of American Physicians and by Dr. Eugene Dong, Jr., a Stanford associate professor of cardiovascular surgery.

The complaints alleged that Stanford's system violated the law because its faculty physicians charge professional fees for services rendered to patients, and then turn the fees over to the medical school to help finance the school's clinical teaching program.

They claimed that Section 2008 of the California Business and Professions Code prohibited physicians who are employed by medical schools in the State from participating in this kind of system.

Dr. Robert Weinmann, president of the Union's local 7402, and Dong spoke in opposition of SB1113 at hearings conducted by the Assembly Health Committee on July 9.

Presenting testimony at the hearing in favor of passage were Stanford University President Richard W. Lyman, Crowley, and pediatrics department chairman Dr. Irving Schulman.

In addition to Stanford, the bill was strongly supported by the University of California and the University of Southern California.

The bill passed the committee by a vote of 11 to zero with one amendment, that a medical school may bill for services only if the faculty physician who provided the services approves of the charge.

That amendment received the concurrence of the Senate by a vote of 28 to zero on July 19, the final legislative step before going to the Governor.

STANFORD—

Partners of couples enrolled in a home study weight loss program can be very influential in assisting their mates in losing weight, according to a new Stanford University study.

Dr. David R. Black of the Stanford Heart Disease Prevention Program said the results of the study involving 33 couples were "surprising" because it was previously believed that it is the participant **not** his or her spouse who could best influence weight loss.

"The partner's beliefs and expectations about doing certain things to help the participant and the importance of these tasks . . . were the best predictors of the spouse's weight loss after three months of participation."

Black and co-investigators Dr. Craig K. Ewart and Judy K. Black found that 40 percent of the couples in the program had unhappy relationships. However, the status of the relationships had no significant influence on weight loss, but was "suggestive" of how much weight would be lost, he said.

The amount of weight loss for all participants was about a third more than would be expected by conventional behavior weight loss methods that did not involve the spouse. Black cautioned, however, that the real objective is to reach an "ideal" weight and maintain it. Data are currently being gathered on this issue.

If the preliminary findings from the study are upheld, Black said there are several possible implications. For example, he said, for couples with unhappy relationships better communication methods should be included in the treatment program. In addition, partner attitudes seem worthy of more attention and ways to heighten both partner and participant beliefs and expectations should be developed, Black explained.

Results of the Stanford study were presented by Black at a recent meeting of the American Psychological Association in New York City.

STANFORD—

A new program for women who have had mastectomy for treatment of breast cancer will be offered this fall at the Stanford University School of Medicine.

The goal of the program is to diminish or prevent the "sexual disability" which results from loss of a breast in many women.

"This is a long-neglected area of treatment," says Reggie Kriss, a licensed counselor who will direct the program.

Learning to face death has been the main focus of psychological counseling of breast cancer patients. Yet, Kriss says, being able to cope with an altered self-image is equally important to post-mastectomy women.

Kriss is seeking 100 women who have had a mastectomy to participate in a year-long program of group counseling.

Beginning in November, two groups of 10 women each will meet every week for the first six months, and monthly thereafter during their year in therapy.

Two new groups will start at six month intervals over a five year period.

A questionnaire developed by Kriss and Dr. Helena Kraemer, associate professor of psychiatry, will measure how effective the therapy is in helping women reconstruct healthy images of themselves and their sexuality.

The program is supported this year by funding from the Department of Psychiatry and Behavioral Sciences and by private donations.

Kriss says that the association between mastectomy and divorce or break-up is well known.

"I believe that if women view themselves as damaged goods, they will give nonverbal signals which may adversely affect relationships," she says.

"Sexuality is a global concept—an essential part of one's feeling of aliveness."

Unfortunately, Kriss says, society teaches women that sexuality is only associated with certain parts of their bodies. "Women have regarded themselves as they think the male sees them," she adds, "never as they see themselves."

Yet it is only women who can make themselves feel whole again after mastectomy.

The advantage of group counseling, Kriss says, is that "feelings come out in the open that women have never expressed before, even to themselves."

In addition, women can help each other find ways of dealing with sexual or marital conflict, and they can encourage each others' self growth.

Kriss is well suited to lead the program, for she has had two mastectomies herself. She has led groups of breast cancer patients with Drs. Irvin Yalom and David Spiegel in the Department of Psychiatry for the past four years, and recently completed training in the sex and disability unit at the University of California School of Medicine at San Francisco.

Ideally, she says, the program will provide new information to help women prepare for the adjustments they will have to make after surgery.

In addition, the program may provide a more effective means of dealing with changes in body images and sexuality which result from all kinds of surgery, injury or disease, she said.

Women interested in participating in the program should call Reggie Kriss at 415: 321-2030.

Details follow asterisks

STANFORD—

Treatment of brain abscesses, biochemical causes for depression and overcoming some forms of diabetes are among the projects of seven young scientists at Stanford University School of Medicine.

Their research is funded by the Biomedical Research Support Grant provided to Stanford by the National Institutes of Health, and administered by a Stanford faculty committee.

The grant helps young scientists establish research programs in areas of basic and clinical research.

The seven assistant professors recently awarded one-year grants are Dieter Enzmann, M.D. (radiology); Richard Mamelok, M.D. (medicine); Abdul Matin, M.D. (medical microbiology); Ronald Merrell, M.D. (surgery); Peter Sargent, Ph.D. (structural biology); Howard Schulman, Ph.D. (pharmacology); and Robert Fowles, M.D. (medicine).

* * * * *

Treatment for brain abscesses often requires surgery but the early inflammation responds to simpler antibiotic therapy. Enzmann is testing computerized tomography scanning (a new method of imaging using x-rays and computers) for distinguishing stages of brain abscess development. Reliable diagnosis of the inflammatory stage could make antibiotic treatment possible more frequently.

Adriamycin, a potent anti-cancer drug, is useful in treating many tumors, lymphomas and leukemias. But a side effect sometimes causes muscle tissue in the heart to undergo permanent changes that may lead to heart failure. Fowles will examine why this happens, how it might be prevented and whether there are possible antidotes that could be administered with adriamycin to counteract these effects.

Mamelok hopes to characterize transport systems in kidney cell membranes, particularly those systems that transport drugs. This could provide additional information on drug therapy in patients with kidney failure, and how to avoid damage to the kidneys when administering potentially toxic drugs.

Matin is examining structurally and functionally similar bacterial proteins known as isoenzymes to discover how and why their synthesis is regulated in cells. When grown in a nutrient-rich environment, one form of enzyme is synthesized but in a less rich environment another form takes over. He will explore how and why such dual systems function.

Sometimes the pancreas must be surgically removed to control certain types of infections—diabetes is the result. Merrell is working on a technique to isolate the healthy, insulin-producing tissue from the pancreas (known as islet tissue) and eventually restore it by injection in the portal vein of the bloodstream. The healthy islet cells lodge in the liver where they produce normal insulin, reversing the diabetic condition.

Sargent studies the formation of synapses, the areas where nerve cells come into close proximity and influence each other across gaps of just one millionth of an inch. Learning how synapses are formed during development will increase knowledge of how they function, the key to understanding how the brain works, according to Sargent.

Many mental diseases may be associated with defects in the process of synthesizing neurotransmitters, chemicals used by nerve cells to transmit information. There is evidence that histamine, a neurotransmitter in the brain, may be involved in depression. Schulman will be studying the synthesis and localization of histamine in the brains of rats.

STANFORD--Dr. Norman E. Shumway and members of the heart transplant team at Stanford University Medical Center this week urged the federal government to officially approve coverage by Medicare of the costs involved with heart transplantation.

In a letter to Henry Hehir, director of medical services policy at the Health Care Financing Administration (Health, Education and Welfare Department) dated September 17, the physicians argued that cardiac transplantation represents the only effective treatment for a select group of patients with end-stage heart disease.

"Furthermore," theystated, "it is absolutely necessary for their survival beyond a few months."

The letter was signed by Shumway and Drs. Edward B. Stinson, Philip E. Oyer, Bruce A. Reitz, and John S. Schroeder.

The costs of heart transplantation have never been covered officially by Medicare, but it has paid for selected aspects of the care of patients receiving the surgery for several years.

Recently, however, the Medicare Bureau began to question whether it can continue to cover a procedure which is considered in many centers to be "experimental," and therefore not "reasonable and necessary for the diagnosis and treatment of illness."

As a result of the uncertainty, independent third party insurance carriers, including Blue Cross and Blue Shield, in some states have decided to discontinue to pay for heart transplantation.

What this means, at Stanford at least, is that patients who are not covered by insurance, and who have limited financial resources, are not eligible to be evaluated for possible heart transplant.

ATTENTION: LARRY ALTMAN

NEW YORK TIMES

Sent business wire
Sept 20

The hospital costs associated with heart transplantation include laboratory, medicines and operating room costs, and a hospital stay of several months, and can total $60,000 per patient.

Some of these costs are paid for by a $1 million-a-year government research grant to Stanford University.

In addition, none of the doctors associated with the transplant program at Stanford charge professional fees for their services to patients receiving transplants. That could add as much as $20,000 extra to the bill, says Shumway.

Nevertheless, costs to the patient can run into the tens of thousands of dollars.

"It is simply not fair or ethical for ability to pay to be a factor in determining whether a patient is evaluated for heart transplant or not," said Lois Christopherson, chief clinical social worker in charge of the cardiac transplant program.

But this is what is happening, she added. Some patients referred to Stanford for evaluation have not been able to come because they were not covered by insurance.

Without continued government and private insurance coverage, the number of patients receiving heart transplants at Stanford each year conceivably could drop from 20 to only four, she said.

Cardiac transplantation has been performed in humans for only 12 years. Many centers which took up the procedure in the early 1970s later abandoned it, because of lack of success. However, survival rates of patients transplanted at Stanford have remained consistently high during the past five years.

Sixty-five percent of patients are alive one year following transplantation; five year survival is 50 percent.

In comparison, over 90 percent of 28 patients who were accepted as candidates but for whom no donor hearts could be found died within three months of their acceptance, stated the doctors in the letter.

The doctors added that cardiac transplantation can be considered to be more successful than cadaver kidney transplantation, which is covered by Medicare.

One year survival of human cadaver kidneys, according to the 1977 Human Renal Transplant Registry, was 46 percent, compared with 65 percent one-year survival of cardiac transplant patients at Stanford the same years.

(Survival of the patient, of course, implies that the transplanted heart has survived).

Congress requires that Medicare cover kidney transplantation, which costs between $15,000 and $25,000 per patient for the first year.

But whereas heart transplantation is the only effective treatment in patients selected for such, hemodialysis is a possible alternative to kidney transplant in most patients with end-stage kidney disease, the doctors stated.

Finally, heart transplantation may actually save society money, by enabling recipients to return to work.

"Among the 78 patients (transplanted since 1974) who survived for greater than one year after operation, more than 90 percent were considered rehabilitated both physically and emotionally," they stated.

"They had the real option of returning to their former mode of employment or engaging in some other productive endeavor."

Examples include one recipient who is a professional bowler, and another who teaches at a state university.

Shumway and his colleagues have not yet received a response from the government to their letter. However they have sent letters to other heart transplant programs throughout the U.S., urging them to make similar appeals to the government, to decide in favor of covering the procedure under Medicare.

STANFORD—

Stanford University School of Medicine has been successful, despite changes in admissions procedures related to the Supreme Court decision in the Bakke case, in attracting qualified minority applicants for the entering class this fall.

Twenty-two percent of the students in the 86-member incoming class represent minorities--black, chicano, and native American.

(The University previously reported a record number of blacks and chicanos enrolling as freshmen and as law students this year).

"The Medical School has made a good adjustment to the Bakke decision," said Acting Vice-President and Dean Dr. Lawrence G. Crowley.

"Presently there is a single admissions committee incorporating the selection of all students. By all indications we continue to attract highly qualified minority applicants," he added.

In addition, 31 percent of the students in the entering class are women. The percentages for both minorities and women are slightly higher to those of past years.

Coupled with Crowley's announcement, a study of minority admissions published in the current issue of the *New Physician* magazine ranks Stanford fourth in performance among 121 medical schools in the area of minority admissions.

The study is based on enrollment figures compiled by the Association of American Medical Colleges directory for 1978-79.

"Only 10 of the 121 predominantly white medical schools in the country enroll over 15 percent minorities, and 43 percent have minority enrollments under five percent," the magazine reported.

Among the medical schools listed by the magazine as having the best score card in minority admissions are University of California-Irvine, University of New Mexico, Michigan State, and Stanford. The University of California-San Francisco ranked seventh, and Harvard eighth.

The study excluded medical schools that are predominatly black—Meharry, Howard, and Morehouse.

In June 1978 the U.S. Supreme Court delivered a 154-page decision declaring the University of California-Davis quota system illegal and ordered 38-year-old Allan Bakke admitted to medical school.

The decision was not a clear-cut one because even though the court rejected outright quota systems, it upheld the use of affirmative action programs in general to improve educational opportunities for minorities.

As a result of the Bakke decision, Stanford as well as other medical schools abolished their special admission committees established to screen and admit minority applicants, and placed all admitting functions into a single committee.

There was apprehension at that time among minority groups that this move would signal the end of affirmative action in medical school admissions.

But Dr. John Steward, associate dean for student affairs, said that concern in the case of Stanford Medical School does not appear to have been justified. He said the school received 5,850 applications this year—300 more compared to previous years. More than 580 of the applicants were minority students compared to 489 the previous year.

"In recent years most medical schools have been experiencing a decline in the overall applicant pool," he added.

Steward characterized the minority students in the entering class as "exceptionally strong with regard to academic preparation, and academic potential for creative careers in the health sciences."

More than 48 undergraduate institutions are represented in the total incoming class. Universities which contributed four or more students to the class include the University of California-Berkeley; University of California, San Diego; Yale, Harvard, MIT, Princeton, and Stanford.

Ten of the students in the first-year class have advanced degrees (M.A., Ph.D.) in other fields.

The incoming class brings to 372 the total number of students in all classes of the Medical School.

STANFORD—

A new device, developed by Stanford University engineers, is aiding scientists at Stanford Medical School and the Palo Alto Veterans Administration Medical Center to understand human liver diseases such as cirrhosis.

The device is called a pulsed Doppler flowmeter, and it works by bouncing sound waves of a certain frequency off red blood cells moving through the vessels which supply the liver, and analyzing the changes in frequency of the echoes.

Cirrhosis is the progressive killing and hardening of liver tissue caused by overuse of alcohol and other drugs, or viral infections such as hepatitis.

The disease can lead to high blood pressure, or hypertension, in the portal vein which feeds into the liver, as it meets increasing resistance to blood flow.

If untreated, this hypertension can result in "catastrophic hemorrhaging" due to overloading and rupture of small vessels outside the liver, says Dr. Malcolm F. Anderson, assistant professor of radiology at the Stanford Medical School.

One third of the deaths due to cirrhosis, he says, is due to massive internal bleeding.

Anderson and his colleagues at the Palo Alto VA Medical Center are studying the development of high blood pressure in the portal veins of dogs, as a model of the human condition.

Blood flow through the portal vein and hepatic artery of the liver is monitored by the flowmeter, which can be completely implanted in the animals.

The 16-cubic-centimeter unit is powered by tiny batteries and transmits its information in the form of electromagnetic waves to an external receiver.

The transmission of physiological information is known as biotelemetry.

The device was designed by Drs. Henry Allen and James Knutti, and Professor James Meindl, engineers at the Stanford Center for Integrated Electronics in Medicine, under a grant from the National Institute of General Medical Sciences.

The great advantage of the new flowmeter, says Anderson, is that it permits measurement of long-term changes in the liver's blood flow.

Previous methods of recording blood flow usually were doneduringsurgery, when the animals were anesthetized, or else required the placement of wires through the skin, increasing the chance of infection.

In contrast, Anderson has been able to monitor dogs for over one year, without infection, while they were awake and active.

He says the goal of the study is to characterize the blood flow changes produced by high blood pressure in the portal vein, and ultimately to help improve surgical treatment of this condition.

The research is supported by grants from the National Heart, Lung and Blood Institute, and the Veterans Administration.

STANFORD—

Superior athletic performance or habitual exercise does not guarantee protection against sudden death during or immediately after exercise, according to a study by researchers at Stanford University School of Medicine.

Regular exercise, such as running or jogging, is generally considered to be healthy for the heart and cardiovascular system. An estimated five to 25 million Americans jog regularly.

However, for some individuals, particularly those with heart disease, the increased workload which exercise puts on the heart can lead to serious problems, and even death.

The Stanford study analyzed the medical histories of 17 men and one woman, who died during or just after jogging or running, between 1973 and 1978.

All but four had been exercising regularly for at least a year, and three of the men had been running more than 100 miles a month. However, two had exercised less than one month when they died.

The study, published in the September 21, 1979 issue of the *Journal of the American Medical Association*, was conducted by researchers at the Stanford Heart Disease Prevention Program, including Paul D. Thompson, M.D., Michael P. Stern, M.D., Paul Williams, M.S., Kirk A. Duncan, M.D., William L. Haskell, Ph.D., and Peter D. Wood, D.Sc.

Thompson is now at Brown University Medical School in Providence, R.I.

The victims, most of them in California, were identified from the obituary accounts and by word of mouth.

Thirteen of the 18 individuals died of documented coronary artery disease. Of the remaining five, three died of heart-related dysfunctions, one died of heat stroke, and one of unknown causes.

In an interview, Haskell said that several factors may have contributed to the deaths of the individuals in the study:

• the majority had preexisting, and severe coronary artery disease, as determined by autopsy, and all of the individuals with heart disease were over 40. Three of the individuals had family histories of coronary artery disease appearing before age 50. Three were being treated for hypertension, and on the average they had a higher-than-expected blood pressure.

• six of the individuals had smoked cigarettes in the past, although all but two had quit the habit several years previously.

- more -

• six (33 percent) of the individuals experienced potential warning signs of heart trouble, but ignored them, and continued their usual level of exercise. Symptoms reported included stomach pains and unusual difficulty with breathing.

One man, who experienced difficulty breathing during a work-out, nevertheless "raced his wife over the final distance to their home, where he collapsed," stated the researchers.

The researchers emphasized that this study does not invalidate the contention that regular exercise, such as jogging, is a valuable health-promoting activity for the vast majority of Americans.

Unfortunately, they stated, "there is no highly sensitive or specific way to identify those at risk of exercise-related deaths." Further study is needed to determine who will benefit from a vigorous exercise program.

For example, most of the individuals in the study had been seeing their doctors regularly. Their cholesterol and triglyceride levels were normal or only slightly elevated.

Nine of the individuals had had exercise electrocardiograms (ECGs), a test of heart function, however, in six, the tests were considered normal.

"There is no evidence in our study that any currently available diagnostic procedure would have prevented these deaths," Haskell said.

"In the past, we considered the start of an exercise program as the high risk period for cardiovascular as well as orthopedic complications, and advised middle-aged men to start exercise programs gradually," the researchers stated.

"However, this study indicates that even long-time exercises are not totally immune to sudden cardiovascular complications."

In addition, they said, "physicians should be certain that their exercising patients are aware of symptoms (of heart problems) and the need for prompt medical attention when these symptoms occur."

And while improvements in diagnosis may identify those individuals at greatest risk for sudden death during exercise, "the ultimate prevention of most exercise-related deaths depends on the prevention of coronary arteriosclerosis," they stated.

(Editors: A photograph of Bonesio is available if not included with the release)

STANFORD—

It seems nothing can stop Louis Bonesio.

At 45 the Gilroy, Calif., resident lives a life of what he calls "constructive leisure" by sailing, riding in hot air balloons, motorcycling and driving a high-powered sportscar.

This might not seem unusual, except that Bonesio is alive because the heart of another human beats in his chest.

Bonesio was 38 when his first heart attack hit. He believes the attack was partly due to the pressures of operating a wine business which, he said, is "at the mercy of the weather, and the whims of the public."

The attack kept him in Veteran's Administration Medical Center in Palo Alto for eight months. Since then he has become one of Stanford University Medical Center's 10 longest-living heart transplant patients.

"I thought the last person in the world to have a heart attack would be me, or so I'd always thought," Bonesio recalls. "I used to smoke, but I had to quit. And, when they told me I should have a transplant, I thought the whole idea was preposterous!

"I told the doctors that I didn't care to have the transplant, and that I didn't like the odds.

"But then I started running out of energy. I'd been in the hospital for more than eight months and I couldn't see my kids very often. They were only eight and four at the time and it was hard for them to understand what was going on."

On May 11, 1974, Bonesio underwent the four-hour surgery that replaced his failing heart. He was Stanford's 71st heart transplant recipient (Stanford has now transplanted 175 patients since the first one on Jan. 6, 1968. Of these patients, 69 are currently alive).

"I was truly surprised when I woke up," he recalled. "But I told myself I would not give up."

And he didn't. Three months later Bonesio was out of the hospital, and started his life over again.

Since the transplant, Bonesio says, "emotions don't fire me up as much now. But that has its advantages too. Now I 'weigh' everything first. That fits my birthsign anyway--I'm a Libra."

The long hospital stay caused permanent atrophy to Bonesio's leg muscles, and if he tries to run his legs bruise badly.

"I used to run track in school," he reflected. "I wanted to play tennis and racquetball. There's no way I can do that now, but what the hell? I'll make that sacrifice."

- more -

The medications Bonesio takes to combat rejection of the transplant--prednisone and imuran--caused some damage to his bones. His vertebrae have decreased in size and he subsequently shrank from five-foot-eleven to five-foot-nine.

"Now I feel like I'm standing in a hole when I'm with my old friends," he quipped.

The prednisone also caused bone degeneration and he was forced to have his hips replaced two years ago. A few months after that surgery Bonesio again returned to the hospital, this time with four broken ribs.

"I was motoring a bit too fast in a construction zone, turned a corner, lost control and hit a parked car," he recalled. "I totalled my Porsche. While I was in the hospital I got a herpes infection. I guess 1977 was not a good year," he laughed.

But Bonesio believes the key to survival lies in his attitude.

"Damn it, I'm not going to quit."

Bonesio tries to instill a similar attitude in others. He works with social workers in the heart transplant program, and talks to potential patients about all aspects of the experience. In addition, he also occasionally meets with Bill Van Buren, Stanford's longest-living heart transplant patient.

Bonesio said he has no problem at higher altitudes, and usually flies when he travels abroad.

"The only problem I have is at the airports. The authorities always want to know why I'm carrying around so much 'dope,' and the metal in my hips sets off the detectors."

Surprisingly, Bonesio doesn't get travel fatigue even though he still gets by with only three to four hours of sleep a night ("a lifelong habit," he says).

Active in community affairs, Bonesio serves on the board of directors of the Gilroy Chamber of Commerce and the Santa Clara County Chapter of the American Heart Association. He is also a member of Gilroy's Elks Lodge, and American Legion Post 669.

STANFORD—

Dr A Dale Kaiser professor of biochemistry, has been appointed chairman of the department of biochemistry at Stanford University School of Medicine.

Kaiser succeeds Dr I. Robert Lehman, who resigned last month to resume full-time teaching and research.

The appointment, effective September 1, was announced recently by Dr. Lawrence G . Crowley, Acting Dean of the Medical School.

Kaiser, who has been a member of the department since 1959, "is one of the world's outstanding scientists," said Dr. Arthur Kornberg, Nobel laureate and professor of biochemistry.

His pioneering work with the bacteriophage lambda, a virus which invades bacteria, led to better understanding of how viruses infect cells, and how their genes are inserted into those of the host.

In 1970, Kaiser received the U.S. Steel Foundation Award in Molecular Biology by the National Academy of Sciences (NAS) in recognition of his work.

Kaiser is now studying the control of development in the social bacterium, *Myxococcus xanthus.*

In addition to his research achievements, "he is a very devoted and excellent teacher," Kornberg said. "He is sought out for advice and guidance by graduate students at all levels of training."

A native of Ohio, Kaiser, 51, received his Bachelor of Science degree from Purdue University in 1950, and his doctoral degree in biology at California Institute of Technology in 1955.

He was a fellow of the American Cancer Society at the Pasteur Institute in Paris, France from 1954 to 1956, and taught in the department of microbiology at Washington University School of Medicine in St. Louis before coming to Stanford in 1959.

Kaiser is a member of several societies, including the NAS, and the American Academy of Arts and Sciences. He has authored over 70 publications, and is on the editorial board of the *Annual Review of Genetics.*

His administrative responsibilities have included membership on the University Committee on Research, and on the University and Medical School Senates.

EDITORS: Details follow asterisks.

FOR IMMEDIATE RELEASE

STANFORD --

Stanford University faces fines totalling $3,585 for alleged violations of health and safety regulations, state officials told the University informally Thursday, Sept. 13.

The University may appeal after official notification is received later this month. In June, Stanford University Hospital was cited for violations carrying a total fine of $1,800.

Repeated violations in the future could carry much greater fines.

The proposed fines against the University include:

* $1,000 for having containers of chemical carcinogens (cancer causing agents) stored outside a regulated area in chemistry, physics, and the Medical School;

* $1,000 for leaving a small vinyl chloride container unused in a chemistry lab;

* Two $500 fines for failing to report the location of two of the carcinogens and vinyl chloride to government officials;

* $235 for failing to post proper notices and follow other regulations for carcinogens kept in locked cabinets, drawers and shelves at the Medical School and in chemistry;

* $140 for failing to properly secure containers of concentrated acids and bases in a physics laboratory;

* $140 for failing to promptly clean up a barium oxide spill in physics; and

* $70 for seven instances of unchained gas cylinders in Plant Services, physics and chemistry.

Jack Sidlow, University manager of health and safety, said many of the violations already have been corrected. Others can be done soon. Most have 30 to 60 day abatement periods.

None involved any allegations of injury to individuals.

* * *

Lawrence S. Wong and John McGuire, state industrial hygenists, found 18 technical violations during 10 visits to campus over the last five or six months.

They indicated Stanford was "pretty much the same" as other universities, although "for the size of the staff, you've done a pretty good job." Health and safety officers often have a tough time "getting through" to researchers on the importance of safety procedures, they noted, UC-Berkeley was similarly cited in June.

(more)

The officials comments and informal discussion among University administrators afterwords pointed up the need for Stanford to establish at least one central storage facility for chemical carcinogens. This requires negative air pressure (to prevent release of carcinogens), careful posting of procedures, and training of users according to federal and state rules.

Fourteen chemicals are covered by these rules:

1. 2-Acetylaminofluorence
2. 4-Aminodiphenyl
3. Benzidine (and its salts)
4. 3,3'-Dichlorobenzidine (and its salts)
5. 4-Dimethylaminoazobenzene
6. alpha-Naphthylamine
7. beta-Naphthylamine
8. 4-Nitrobiphenyl
9. N-Nitrosodimethylamine
10. beta-Propiolactone
11. bis-Chloromethyl ether
12. Methyl Chloromethyl ether
13. 4,4'-Methylene (bis) 2-chloroanilinc
14. Ethyleneimine

The University of Colorado already has four high containment facilities for these carcinogens, Sidlow noted. SRI International handles these materials well, Wong and McGuire indicated.

Several of the violations cited at Stanford involved materials which were seldom used, Sidlow said. "For safety's sake:

* "It's important for all laboratories to let the Health and Safety Office know the location and amounts of carcinogenic chemicals used in research.

* "When these materials are rarely used, they should be disposed of promptly and properly.

* "When noncarcenogenic alternatives are available, these should be used.

* "Even small amounts, improperly stored or accounted for, can result in substantial penalties. Fines can be doubled if similar violations are found anywhere on campus within three years."

Special care also is indicated for such substances as asbestos, acrylonitriles, and arsenic compounds, Sidlow added. The number of hazardous materials probably will grow with time.

Although state and federal rules were designed to cover large quantity users, such as industry, they offer no special consideration to research or teaching institutions.

The review of Stanford compliance with CAL/OSHA (California Occupational Health and Safety Administration) rules is believed to have been triggered by employee concern over spray painting of acoustical ceilings containing small amounts of asbestos at Escondido Village.

(more)

The University was not cited for any violation there. Air samples taken at the site showed extremely low levels of asbestos fiber. The painting was designed to permanently seal the asbestos.

An information memo from the state will indicate the need to clean up asbestos particles promtly, Wong and McGuire said.

This memo also will cover acrylonitrile regulations, which lapsed briefly during the compliance study at Stanford but have been in effect since mid-June.

In 1977, the University organized a biohazards task force. In a report last year, it called for creation of a new Administrative Panel on Chemical Biohazards, said the list of regulated chemical carcinogens should be circulated to principal investigators, and noted that carcinogens should be stored in specifically approved locations.

STANFORD—

An endowed professorship has been established in the Stanford University School of Medicine by a gift from Dr. and Mrs. George H. Becker of San Francisco.

The new chair will provide support for faculty members whose work relates to "the alleviation and prevention of disease," according to acting dean Lawrence G. Crowley, M.D., who made the announcement yesterday for the Board of Trustees.

The chair will be named in honor of Dr. Becker's parents, George E. and Lucy H. Becker. The first holder of the professorship has not yet been named.

In making the gift, Dr. Becker, who practiced internal medicine in San Francisco for many years, said, "My parents and my profession have been very good to me. I would like to show my appreciation in a lasting way."

Dr. Becker is a 1921 graduate of the Stanford University School of Medicine, a diplomate of the American Board of Preventive Medicine and Public Health, and a fellow of the Royal Society of Health in Great Britain.

He has served as director of the Bureau of Communicable Diseases of the San Francisco Department of Public Health, vice-president of the Independent Order of Foresters with responsibility for their tuberculosis hospital and aged residents' home, and a member of the Irwin Memorial Blood Bank Commission.

Dr. Becker's many civic activities include leadership in the Tuberculosis Society, Community Chest, American Legion, United Service Organizations (USO), and the San Francisco Young Men's Christian Association (as president during World War II).

Dr. Becker is also one of the founders of the United California Bank.

Born in San Francisco, Dr. Becker graduated from Lowell High School and received his A.B. in science from the University of California in Berkeley.

He and his wife, the former Miriam Casperson of San Francisco, were married in 1924. They have travelled widely and share many philanthropic interests.

Dr. Becker's father, for whom the professorship is named, emigrated from Germany in the 1880s. He became associated with, and later managed, a San Francisco drayage firm.

His wife, the former Lucy Hanson, who is also named in the title of the chair, was born in San Francisco of Scottish parents. She served as a worthy matron of the Yerba Buena chapter of the Daughters of the Eastern Star.

Dr. Becker remembers his mother Lucy as "a truly remarkable woman. She possessed the rare realization that youth is endowed with a 'Holy Curiosity,' as Einstein put it, and mine was never suppressed."

Although director Dr. Kathryn Beadle is on a 10-month leave, Stanford's Speech and Language Clinic is continuing its many diversified programs.

Donna Dagenais is serving as acting director of the clinic, which deals with speech problems in children and adults. Tutoring for children in small groups is also provided.

A special program for stroke victims has also been offered at the clinic.

The clinic's tutoring program differs from usual clinic therapy. The focus is on specific learning problems children bring home from school, such as homework or concepts they cannot understand. Many of the children have underlying developmental speech and language disorders.

Beadle is serving as associate professor at Los Angeles State University during her leave from Stanford.

FOR IMMEDIATE RELEASE

STANFORD—

"Stanford Medical School—The San Francisco Years," will be the featured presentation at a meeting of the Stanford Historical Society on Sunday, November 4 at 3:30 p.m. in Fairchild Auditorium.

Dr. Alvin Cox, emeritus professor of pathology in the department of dermatology, will present the talk which is open to the Stanford community and the public.

Stanford's School of Medicine originally was a private school in San Francisco known as Cooper College.

In 1908 the properties of Cooper Medical College were transferred to Stanford. All of Stanford's medical and clinical training took place in the San Francisco facilities until 1959, when the School of Medicine moved to new facilities on the university campus.

This is the 20th anniversary of the medical school's move.

Dr. Cox came to Stanford as a freshman in 1923 and has been associated continuously with the university for 56 years. He has been a faculty member for 46 years and was chairman of the department of pathology for 23 years.

He has done pioneering work in the field of environmental carcinogens and is still active in teaching and research at Stanford.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR INFORMATION CONTACT: Spyros Andreopoulos, 497-6911
FOR IMMEDIATE RELEASE
STANFORD—

The closing of approved radioactive waste disposal sites could affect about 300 research projects at Stanford within a few months, John A. Holmes, the University's senior health physicist, said Wednesday, Oct. 24.

The shutdown will have no immediate effect, since the University sent a shipment to Washington state which was buried there before that site was closed.

Holmes already has asked campus users of radioactive materials to reduce use as much as possible intil the situation is clarified.

The University has three or four shipments a year totaling about 170 55-gallon drums each, Holmes said.

"We're extremely cautious and always use proper disposal techniques."

Prof. Philip C. Hanawalt, biological sciences and chairman of the University's radiological hazards panel, stressed that the hazards from radioactive materials used in university research are miniscule compared to hazards generated by industry.

Stanford recently hosted the annual conference of California campus radiation safety officers. In a letter to Governor Dixie Lee Ray of Washington, the 18 participants urged action to reopen the site.

The letter said:

"Because we have responsibility for radioactive waste disposal from university research programs, we are facing a dilemma as to how such research can continue.

"We may well have to curtail vital medical and biological research on major campuses throughout the state.

"We ask that you not impose unduly restrictive regulations on our ultra low-level wastes which present minimal hazards, in contrast to the much higher activities and concentrations of low level waste from industry.

Similar letters were written by John Hickman, radiation safety officer at UC-Davis, to the governors of Nevada and S. Carolina which is now the only open site.

Among projects that could be affected are research efforts at Stanford Medical Center, Palo Alto Veterans Medical Center, Children's Hospital at Stanford, Carnegie Institute, and Hopkins Marine Station.

Projects include most basic chemical and biochemical research, including recombinant DNA, and cancer therapy temporary implants which use radioactive iridium with a half-life of only 60 days.

In the basic research projects, two commonly used radioactive tracers are Carbon 14 and Tritium. Both are low risk radioisotopes, but have long half-lives, requiring safe storage until they decay.

Radioisotopes used in diagnosis and treatment by nuclear medicine have very short half-lives and could be stored on the campus disposal facility until rendered harmless.

Holmes said Stanford has always taken a very conservative approach and has shipped its radioactive wastes in special containers prescribed by the U.S. Department of Transportation following all burial requirements.

Stanford, he added, could get by for a couple of months storing the wastes in its own facility, and doing everything possible to reduce use.

"But California needs state action to have available a properly operated burial site for radioactive wastes generated by vital biomedical research programs," he added.

STANFORD—

Wanted: pleasant, caring people willing to spend several hours a week helping hospital patients. The pay? None. The rewards? Numerous.

This is not your typical "help wanted" advertisement, but then the Stanford Medical Center Auxiliary is not your typical organization either.

The auxiliary, which provides a myriad of patient-related services for Stanford Medical Center, is seeking additional men and women volunteers for its ranks that have been taxed recently by the uncertain economic climate.

The volunteer organization, which currently has about 350 active members, is hoping to recruit adults (and teenagers for its junior auxiliary) from the peninsula, explained auxiliary president Ann Markevitch.

"In a time when many people are seeking paid work due to economic necessity, they may forget that they can still give a few hours each week on a volunteer basis," Markevitch noted. "Unlike many activities, it (the auxiliary) brings a lot of satisfaction and friendship as well."

The auxiliary is celebrating its 50th anniversary this year, and in that time its members have logged some 1.4 million hours of service. Although the auxiliary was originally formed at the old Palo Alto Hospital, it became the Stanford Medical Center Auxiliary when the present university medical center site opened in 1959.

"Our auxiliary provides us with an invaluable service," commented hospital administrator Gary Mecklenburg.

"Its many services are all designed to assist us in the care of our patients, to make their stay in the hospital a more comfortable one. Auxiliary members provide that very important 'human touch' in the care our patients receive.

"In an era of heavy emphasis on cost containment, the auxiliary maintains 'extra services' that might be given up in a tight budget."

Mecklenburg noted that the auxiliary annually donates thousands of dollars worth of equipment for nursing units and departments in the hospital and medical center. In addition, it has provided nearly $155,000 in short-term loans to young interns and residents since 1962.

The auxiliary also provides two annual scholarships, one for an outstanding junior volunteer, and the other to Stanford Medical School, which in recent years has been awarded to a second year student in the master's program of the Division of Physical Therapy.

Auxiliary members work in the volunteer organization's 14 different services in the main medical center and at Hoover Pavilion, which is also a part of Stanford Hospital located near the Stanford Shopping Center.

Peninsula residents interested in joining the Stanford Medical Center Auxiliary may call (415) 497-6636 weekdays. Orientation meetings for prospective members are held the first Saturday and third Wednesday of each month.

EDITORS: ADVANCE FOR PM RELEASE ON WEDNESDAY, OCTOBER 24, 1979

STANFORD—A study by researchers at Stanford University School of Medicine and the American Dental Association has found important health problems among dentists and their assistants, associated with the use of anesthetic gases.

The problems include increased rates of liver, kidney, and neurologic disease, increased numbers of miscarriages among wives of male dentists and among female assistants exposed to trace concentrations of the gases, and a greater incidence of birth defects in the children of exposed female assistants, compared to those not exposed.

The implications of these findings are of concern to the health of approximately 100,000 dental personnel who are exposed to anesthetic gases in the U.S., said Dr. Ellis Cohen, professor of anesthesia at Stanford. However the results observed could be influenced, as in any epidemiologic survey of this type, by unrecognized reporting biases within the study respondents.

The findings were reported October 24 at the annual meeting of the American Society of Anesthesiologists in San Francisco, and presented simultaneously in Dallas at the annual American Dental Association (ADA) meeting by William Greenfield, DDS, chairman of an Ad Hoc ADA Committee on trace anesthetic gases.

The study, which is supported by grants from the National Institute for Occupational Safety and Health (NIOSH), began in June, 1978, and is scheduled for completion next year.

Questionnaires were sent to 64,000 dentists and dental assistants. Respondents were asked to estimate their occupational exposure to anesthetic gases, such as nitrous oxide and halothane, and to complete a brief personal health history for the 10 year period, 1968-78.

Over 22,000 dental assistants and 21,000 dentists responded to the survey, and 23,000 pregnancies which occurred during the sample period were reported.

Among the dentists who responded, 42 percent said they used anesthetic gases regularly in their practices. Approximately one-third of that group were "heavy users," using the agents more than nine hours per week.

The study found:

• among heavily anesthetic-exposed dentists, an increase in liver disease from 1.9 to 3.2 cases per 100, an increase in kidney disease from 2.4 to 2.9 cases per 100, and an increase from 0.35 to 1.35 cases per 100 in non-specific neurological disease (numbness, tingling, and weakness) relative to the group reporting no exposure to the anesthetic gases.

-more-

• among heavily exposed female dental assistants, an increase in liver disease from 1.0 to 1.6 cases per 100, an increase in kidney disease from 2.4 to 4.1 cases per 100, and an increase in non-specific neurological disease from 0.45 to 1.98 cases per 100 relative to the non-exposed group of assistants.

• the rate of spontaneous miscarriage was increased from 6.7 per 100 in the control group to 11.0 per 100 among wives of heavy anesthetic-exposed dentists, and from 7.6 cases per 100 in the non-exposed to 17.5 cases per 100 in heavily exposed female dental assistants.

• birth defects increased from 3.6 to 5.9 per 100 among children of exposed female assistants, however, no increase in birth defects was reported in children of exposed male dentists.

• cancer incidence was unchanged among male dentists, but the rate among exposed female assistants appeared somewhat higher than among those unexposed.

A study of individual anesthetic gases used in dental offices revealed that nitrous oxide was the sole agent reported by 81 percent of those dentists using anesthetic gases.

Nitrous oxide, commonly known as "laughing gas," has always been considered to be inert and nontoxic. However, this study indicated that "significant health problems appear to be associated with the use of nitrous oxide alone," Cohen said.

It is presumed that patients themselves are not at risk because they are exposed only briefly to the anesthetic agents. The present study was designed to investigate dental personnel who are chronically exposed to trace concentrations of anesthetics.

Because dentists work close to the patient's open mouth, and tend to use larger volumes of the gases to maintain effective anesthesia, they may receive two to three times the dose of anesthetic gases as operating room personnel, said Cohen. Fortunately, control measures are available which assist substantially in reducing dental anesthetic exposure to acceptable levels.

Stanford and the ADA began the research at the request of the National Institute for Occupational Safety and Health after a similar study by the American Society of Anesthesiologists in 1974 revealed increased rates of liver disease, kidney disease, miscarriage and birth defects among male and female hospital operating room personnel, and increased rates of cancer among female personnel exposed to trace amounts of anesthetic gases. Subsequently, the ADA, working together with the ASA, alerted its membership to a similar potential problem in dental personnel.

In addition to Cohen and Greenfield, the research was conducted by Dr. Byron Brown and Ms. Marion Wu, of the Division of Biostatistics at Stanford Medical School, Drs. Charles Whitcher and Jay Brodsky, of the Stanford Anesthesia Department, Dr. Helen Gift, director of Economic Research of the American Dental Association, Dr. Thomas Jones, of the Department of Oral and Maxillofacial Surgery, University of Alabama, and Dr. Edward Driscoll, consultant for the National Institute for Dental Research.

STANFORD—

Health hazards associated with sports will be explored by six Stanford University physicians in the autumn Progress in Medicine Lectures sponsored by Stanford School of Medicine.

"Sports Medicine" will be the subject of the three successive Tuesday lectures beginning Oct. 30. Each talk is open to the public and will begin at 7:30 p.m. in Kresge Auditorium at Stanford Law School on campus.

Drs. William Haskell and Peter D. Wood will discuss "At the Starting Line," a review of the physiology, body conditioning and nutrition for sports participants, in the first lecture Oct. 30.

Haskell is associate clinical professor of medicine in the Stanford Heart Disease Prevention Program, while Wood is adjunct professor of medicine, and deputy director of heart disease prevention.

"From the Heights to the Depths," a look at the special joys and dangers of skin diving, climbing, skiing, and scuba diving will be discussed by Drs. Herbert N. Hultgren and Alfred Spivack on Nov. 6.

Hultgren is professor of medicine and chief of cardiology services at Veterans Administration Medical Center in Palo Alto, while Spivack is clinical professor of medicine.

Drs. K. Gordon Campbell and Michael Dillingham will discuss "On the Playing Fields," a review of contact sports, racquet games and running, on Nov. 13.

Campbell is clinical associate professor of surgery and an orthopedic surgeon in the Department of Sports Medicine at Palo Alto Medical Clinic. He is also the team physician to the San Francisco Giants.

Dillingham is director of the Sports Medicine Clinic, Division of Orthopedics.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of Stanford Medical School, and by the Medical Center Council.

Although admission is free, seating is limited and will be on a first come basis.

STANFORD—

Stanford medical students performed far better in Part I of the National Board Examinations in 1979 compared with last year, the office of student affairs of the Stanford University School of Medicine said Monday, October 22.

Information distributed to faculty and students by Dr. John Steward, associate dean for student affairs, shows that only 15 percent of the 87 students taking the examination in 1979 failed all or part of it compared to 37 percent last year and 27 percent in 1977.

The percent of medical students failing the entire exam in 1979 was as low as any year among the past nine years, Steward reported.

For the six years prior to 1977 the average percent of students failing all or part of the exam was 15 percent.

Part I of the examination, administered in July and September by the National Board of Medical Examiners, tests knowledge in the basic sciences, and usually is taken after two years in medical school.

Part II of the exam tests knowledge in the clinical sciences. The performance of Stanford students in that portion of the examination has been quite constant over the years. Passing both parts is a requirement for a medical degree at Stanford.

The medical students' falling scores in the basic science examination had caused concern among the faculty last year, even though the reasons for the decline were unclear, according to Steward.

"It is more clear now," he said, "that it is probably related to attitudinal factors. Students did not take the tests as seriously as had previous classes. Studies done last year could not associate the falling performance in 1977 and 1978 with any changes considered by the admissions committee in the selection of students."

Nevertheless, the faculty senate of the School, responsible for the curriculum, took steps last summer to strengthen the system of evaluating student performance.

The measures range from improved counseling of students with marginal performance, better procedures to inform students of their progress, to dropping under certain conditions the failing students from the M.D. program.

Stanford medical graduates have, however, competed extremely well for desired internships, Steward noted.

In 1979 more than 70 percent of the M.D. recipients were successful in obtaining one of their first three choices of internship appointments.

STANFORD—Dr. Otto A. Mortensen, visiting professor emeritus of anatomy at Stanford University School of Medicine, died Thursday, October 18, at Stanford hospital after suffering a heart attack at his home in Menlo Park.

He was 77.

A native of South Milwaukee, Wisconsin, Dr. Mortensen received his M.D. in 1929 from the University of Wisconsin Medical School in Madison.

He joined the Department of Anatomy at the University of Wisconsin in 1930 as an instructor, advancing to full professor in 1946, and chairman of the Department in 1950.

Dr. Mortensen also served as associate dean of the University of Wisconsin Medical School from 1952 to 1967, and continued to teach until he retired in 1972. He came to Stanford that year.

In addition to his teaching activities, Dr. Mortensen served on the National Board of Medical Examiners, Anatomy Section, from 1958 to 1962, and as vice-president of the American Association of Anatomists from 1960 to 1962.

He received the distinguished service award from the Wisconsin Medical Society in 1967, and is listed in *Who's Who in America.*

Dr. Mortensen is survived by his wife, Lila, and three children, Mrs. Margaret Wolberg of Madison, Wisconsin, Dr. Charles O. Mortensen of Muncie, Indiana, and Peter A. Mortensen of Hilton Head, South Carolina.

Memorial services will be held at the Stanford University Memorial Church on Saturday, October 27 at 4:30 p.m. Memorial contributions may be given to the Otto A. Mortensen Memorial Lectureship in Anatomy, at the University of Wisconsin Medical School, or to the Stanford University Medical Student Scholarship Fund.

STANFORD—

Donald R. Thomas has been appointed director of personnel, and William W. Arnold a new assistant administrator, both at Stanford University Hospital.

Both appointments are effective immediately, according to hospital administrator Gary Mecklenburg.

Until recently Thomas served as director of personnel management and employee relations at the University of Pennsylvania Hospital in Philadelphia.

At Stanford Hospital he is responsible for employment, compensation and benefits, employee relations, education and development, employee health, and daily activities of the personnel department.

Arnold was assistant administrator of Santa Barbara Cottage Hospital, where he had responsibilities for a number of administrative programs.

Prior to that he was an administrative resident at the same hospital.

A graduate of Menlo College, Arnold also received a B.A. from the University of Washington in Seattle, and a master's of public health from UCLA.

City Desks: The following story is released jointly by the Children's Hospital at Stanford, and the Stanford University School of Medicine.

STANFORD--

The Children's Hospital at Stanford, and the department of pediatrics of the Stanford University School of Medicine will consolidate their outpatient pediatric services in a single program known as Stanford-Children's Ambulatory Care Center.

The center, which will be located at Children's Hospital on Willow Road across from the Stanford University Medical Center, will encompass all of the outpatient pediatric programs previously divided between the two independent institutions.

The move involving the relocation of the general pediatric clinic and 16 pediatric specialty clinics from Stanford to Children's Hospital is expected to take place in November.

Children's Hospital and Stanford, however, will continue their special inpatient treatment programs, and children seen at the ambulatory care center who require hospitalization will be admitted to each hospital according to need.

The center will be directed by Dr. Ruth T. Gross, McCormick professor of pediatrics and head of ambulatory pediatrics at the medical school.

The agreement to create a full-fledged ambulatory care center in a single location was announced Monday, (October 8) by Harold R. Walt, chairman of the Children's Hospital board of directors, and Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the medical school.

The agreement which took more than a year of negotiations contains provisions to strengthen the joint missions of the two institutions without detracting from their separate identities.

"The medical staff and administrations of Stanford and Children's Hospital desire to provide the best medical care for children," said Walt and Crowley in a joint statement.

"This requires using our facilities, staffs, and equipment to fullest advantage. We believe the development of an integrated Stanford-Children's Ambulatory Care Center is a significant step in this direction," the statement said

John R. Williams, acting executive director of Children's Hospital, noted that the new clinic structure represents a consolidation of programs, and not a merger of institutions. The basic affiliation agreement, linking Children's Hospital and Stanford through a teaching program, remains unchanged.

In the new setting, Children's Hospital will provide space, nursing and support staff and ancillary services, and Stanford will provide medical staff and the postgraduate educational program, he said.

-more-

Dr. Irving Schulman, Kendrick professor and chairman of the Department of Pediatrics, said the move will strengthen the scope and intensity of the long association between the medical school and Children's Hospital.

"The goal," he said, "is to create a strong single children's medical center program with two institutions owned and managed by separate governing bodies but sharing common professional goals."

He described the goals as follows:

- to provide exemplary medical care for children.
- to serve as a regional referral center.
- to provide excellent teaching and training for students, residents, fellows, physicians, and allied health professionals.
- to advance knowledge of diseases of children through research.
- to eliminate unnecessary duplication of facilities and services.

Children's Hospital, an independent nonprofit institution, and Stanford University School of Medicine have maintained close ties for years, according to Walt. In the early seventies, through joint planning, several patient care and research programs directed by Stanford faculty were located there as part of the patient care, education, and research programs of the school.

These included treatment programs for cancer, allergy and immunology, orthopedics and rehabilitation, and child psychiatry.

Pediatric outpatient programs now scheduled to move from Stanford to Children's Hospital in November include the general pediatric clinic and clinics for adolescent medicine, cardiology, endocrinology and metabolism, gastroenterology, genetics, hematology, nephrology, neurology, and surgery.

Dr. Gross, who also heads a general pediatrics training program under the auspices of the Robert Wood Johnson Foundation, said:

"Stanford and Children's Hospital are interested in developing an expanded ambulatory care program in the interests of pediatric care and teaching and training.

"It is only appropriate that we do it in a facility which is adequate to meet the program needs."

Gross said that today's pediatricians are increasingly occupied with a variety of chronic illnesses, handicapping conditions, and disorders of behavior and learning.

"The care of children with these conditions requires the skills of the general pediatrician trained in the ambulatory setting," she said. "Until now the training in general pediatrics has been primarily hospital based."

As a result, Gross said, young pediatricians in training have had less opportunity to become familiar with many of the clinical problems they will deal with in pediatric practice.

"We are taking a much broader view of the health needs of children," Gross said, "by giving greater emphasis on emotional and developmental needs, learning disorders, adolescent medicine, and the impact of chronic disease on children and their families."

Presently, physicians and the administrative staffs of the two institutions are taking steps to keep all patients informed of the move and make the transition as smooth as possible.

STANFORD—

In honor of the International Year of the Child, an open house for the public will be held in the Pediatrics Department at Stanford University Hospital Sunday, Oct. 21, from 1:30 to 3 p.m.

A series of events are scheduled that afternoon by the pediatrics staff to demonstrate child and health care teaching at Stanford.

These include a pediatric orientation, parent-staff discussion on hospitalization, special "play sessions" for children, and health care exhibits.

The event, which will be held in the pediatric clinic area (third floor of the hospital), will also provide an opportunity for the public to meet with health care consultants.

Judy Lanigan, assistant director of Nursing Service at Stanford Hospital, is coordinating the open house, along with Pat Moylan, Betty Lovelace and Judy Cramer.

In addition, Eleanor Hedenkamp and Pat Schnider are planning to develop a series of displays for the hospital with the U.N. International Year of the Child theme.

Reservations by Oct. 17 are encouraged by calling Linda Wong at (415) 497-7540 or 497-5096.

STANFORD—

Stanford University Hospital's West Nursery has been re-opened after undergoing a complete renovation. At the same time, remodeling has begun on the hospital's Neonatal Intensive Care Unit (East Nursery).

The renovation projects, which are costing about $1.6 million, are designed to improve infant patient care. Upgrading of the units will also help the hospital meet tightened state and federal licensing and accreditation requirements.

The remodeled West Nursery, which is primarily for infants in normal health, can house 23 bassinets.

The unit now features additional space between bassinets, well-lit rooms and modern pediatric monitoring equipment, explained Gary Rotzin, associate director of facilities at the hospital and primary project coordinator for the West Nursery renovations.

"We are very pleased with it," he noted, "as are the pediatric nurses on the unit. This represents a major improvement in the care of infants at Stanford."

Drawings for the Neonatal ICU were approved recently by the Offices of Development and Licensing of the State of California. The project, which began earlier this month, should take approximately 10 months, Rotzin predicted.

The Neonatal ICU has been chronically short of space, and the nursing staff threatened to resign en masse about a year ago unless the renovations were made. The situation was complicated when plans for the project were unexpectedly delayed.

In addition to Rotzin, other hospital staffers involved in the West Nursery project were health services planner Betty Rose and Gordon MacLachlan, project coordinator.

STANFORD—"What Can We Do With Pain?," a public seminar on resources available for dealing with pain will be held Tuesday evening, Oct. 16, in Fairchild Auditorium at Stanford University Medical School.

Community clergy, social workers, medical students, members of hospital auxiliaries and allied health professionals are invited to attend the session, which will be held from 5 to 9:30 p.m.

Among the participants will be Stanford University Hospital chaplain Rev. Ernie Young and Dr. Lorne Eltherington, associate professor of clinical anesthesia.

A fee will be charged, which includes a box supper. For further information call the hospital chaplain's office at (415) 497 5101.

STANFORD—

A team of investigators at Stanford University is looking for 400 women volunteers between the ages of 35 and 65 for a study on the changes women experience related to menopause.

Women may qualify if they have noticed changes in their menstrual periods which might indicate menopause is approaching.

These would include recent changes in cycle length or a cessation of menstrual periods, provided the last one occurred within the last two years.

Dr. Winnifred Cutler, postdoctoral fellow in charge of recruitment of participants for the study, says it is one phase of a larger investigation on certain aspects of aging in men and women.

Dr. Julian Davidson heads the aging studies which are being conducted in the department of physiology and are funded by the National Institutes of Health.

"Although menopausal women are subject to biochemical changes at least as great as those of puberty, few large scale studies in this area have been made," notes Cutler.

"This is an opportunity for volunteers to contribute to knowledge on an issue of great importance to women," she adds.

Cutler explains that menopause difficulties represent a relatively recent problem and are apparently unique to humans.

"In the 17th century, less than 28 percent of the female population lived to experience it, and only about five percent reached age 75.

"Today in developed countries, 96 percent of women experience menopause and 50 percent reach age 75."

Some common symptoms of menopausal distress include insomnia, depression, hot flushes and muscle and joint pain, as well as sexual difficulties, Cutler says.

"We hope to learn what changes women experience and to be able to identify those changes that are a consequence of normal aging of the ovary.

"Understanding this relationship is the first step toward the development of an effective treatment of menopausal symptoms," she adds.

Two types of participation are available. In the first, 400 women will be asked to fill out a variety of questionnaires, anonymously and confidentially, during two private interview sessions, each lasting less than an hour.

The interviews will be scheduled several weeks apart and may be conducted in the participant's home or at the Stanford physiology department, according to the participant's choice.

Cutler also needs 20 research assistants to work with her in conducting the interviews The research assistants should commit three hours per week for 12 weeks

The schedule is flexible and can be arranged to suit the needs of the research assistant, she says.

Anyone interested in volunteering should phone the department of physiology at (415) 497-2432 and leave her name and telephone number so that Cutler may return her call.

STANFORD—

Alcoholism among teen-agers represents a serious, and growing problem which demands the intervention of pediatricians as well as parents.

According to Dr. Stephanie Brown, associate director of the Alcohol Clinic at Stanford University Medical Center, between 30 and 50 percent of teen-agers are confirmed moderate drinkers by the time they reach adulthood.

Among adolescents, the onset of alcoholism is extremely rapid. Some young people have become alcoholics within six months of taking their first drink, Brown said.

"And if untreated, the teen-age alcoholic is bound to continue into the adult alcoholic," with corresponding social and physical problems, she said.

Brown spoke to community and Medical School faculty physicians at the Pediatric Department's grand rounds Friday, September 28.

She said one possible reason for the increasing rate of teen-age alcoholism is the fact that many teen-agers have switched from drugs, which are illegal and relatively difficult to obtain, to alcohol, which is more socially and legally acceptable, and which also provides a "high."

"The teen-age drinker may be the inner-city, street-wise kid," Brown said. "Here, drinking often is a part of a network of misbehavior," including delinquency and crime.

But he or she also may be a middle or upper class youth, who exhibits conventional behavior, and is seen by others as a high achiever.

"These teens usually drink in order to cope with the pressures of living," she said. As it is true of most adolescents, they may feel insecure, but they believe that drink will give them what they lack. "Their self-esteem is regulated through the use of alcohol," she said.

Unfortunately, Brown said, even if a drinking problem is spotted in these young people, usually no intervention is attempted, because "they are doing so well."

After all, drinking is the norm for adults. And if adolescents are to continue to see themselves as normal, they must begin to drink.

"This would be less of a problem if we had standards for learning drinking behavior," she said. "But we don't. In fact, drinking among teens is illegal. We have a double standard that actually may contribute to the problem."

-more-

Because teen-agers learn that they must hide alcohol and drink it quickly, lest they get caught, they unwittingly copy the secretive drinking patterns typical of adult alcoholics.

Family problems also contribute to teen-age drinking. The child of an alcoholic is much more likely to repeat the pattern, Brown said.

For some children, alcohol becomes an object replacement for a rejecting or unavailable parent. "These children symbolically ingest that individual when they drink," she said, "and it becomes as difficult to separate them from alcohol as it is to break a close human bond."

Physicians face a tremendous challenge in treating teen-agers with drinking problems. "Often the young person refuses treatment, and denies vehemently that he or she even has a problem with alcohol," Brown said.

Physicians can overcome this denial by beginning with a discussion of the problem areas in their patient's life—difficulties in forming friendships, poor performance in school, or troubles with the police—and relating these problems to drinking.

In addition, it may be necessary to include the family in therapy, particularly if family members have contributed to the teen-ager's drinking problem.

But most important, physicians must accept no excuses from the patient with a drinking problem. "The teen must be treated as a potentially responsible adult who is on the path to self-destruction," Brown said.

Couples in which one partner has diagnosed high blood pressure due to personal or social stress are being sought for a research study at Stanford University Medical School.

According to Dr. Craig Ewart, a psychologist and research associate in Stanford's Behavioral Medicine Laboratory, couples volunteering for the one week study will be interviewed, asked to complete a confidential questionnaire and have their blood pressure monitored during the sessions.

Those volunteers showing "significant changes" upon completion of the week-long testing will be asked to participate in followup training program lasting three additional weeks, Ewart noted.

"We want to show them how the social environment affects their blood pressure, and teach them to cope more effectively with this stress.

"Research shows that social stress may be involved in about 30 percent of today's hypertensives," Ewart explained. "This stress may be caused by a work situation, overbearing and abusive people, distressful marriage--a myriad of things.

"What we want to do is to map the problem of personal stress and its effects," he concluded

Ewart said those volunteering should be able to bring their spouse or mate with them for the sessions. The studies are conducted at no cost.

Those interested should contact Ewart or Dr. C. Barr Taylor at the Stanford Behavioral Medicine Lab, Room TD 205, Stanford Medical Center, Stanford, Calif. 94305. Telephone (415) 497-5065.

STANFORD—

Sleepless nights, declining sexual activity, and loss of memory are not inevitable consequences of aging, according to three Stanford University psychiatrists.

Often, these problems stem from physical disease, or even fulfill social expectations about aging, and therefore can be prevented.

The psychiatrists, Drs. William C. Dement, Herant A. Katchadourian, and Jerome A. Yesavage, spoke Thursday night, November 29 to a full house at the Medical School's Fairchild Auditorium. The program was sponsored by the Friends of Psychiatry and Behavioral Sciences.

About 40 percent of people over age 65 complain about their sleep, said Dement, who directs the Stanford University Sleep Disorders Clinic and Research Center.

Does this reflect that older people are less able to sleep well, or that they simply need less sleep?

"Normal sleep which is deep allows us to be zestful and alert during the day," Dement said. If the need for sleep decreased with age, one would expect daytime alertness to remain the same.

If, on the other hand, the ability to sleep declined, it would be reflected in deterioration of daytime alertness, concentration, and even memory, he said.

This is what is found in many older patients, he added.

Dr. Mary Carskadon, a staff member of the Sleep Research Center, studied the sleep of 24 elderly people who were healthy and had no complaints about their sleep.

Surprisingly, 12 of them exhibited sleep apnea, the cessation of breathing during sleep. This disorder, estimated to afflict between 50,000 and 100,000 Americans of all ages, is characterized by excessive snoring and daytime sleepiness, and can lead to heart disease, stroke, or even death.

Dement said that poor sleep is not a consequence of aging per se, but can be accounted for by disease. "If we can eliminate the disease (in this case by drugs to stimulate breathing during sleep), we conceivably might extend the lifespans of these people," he said.

Similarly, memory loss can be linked to diseases such as atherosclerosis and high blood pressure, said Yesavage, who directs the psychiatric intensive care unit at the Palo Alto Veterans Administration Medical Center.

- more -

In addition, scientists believe that a slow down in the metabolism of brain cells may result in memory loss. Yesavage currently is testing an experimental drug, Hydergine, which stimulates brain metabolism, as a means of improving memory.

Psychological treatments also are important in improving memory, Yesavage said. "Memory can be compared to a muscle. It has to be exercised, otherwise we will forget how to remember things," he said.

Like sleep and memory, sexual activity need not decline as one grows older, said Katchadourian, who teaches "Human Sexuality," the most popular undergraduate course at Stanford in terms of enrollment.

Certain biological changes, and an increase in frequency of disease among older persons, can slow sexual responses, but "nothing fundamentally changes in the older individual," he said.

However, psychological problems, such as depression, and even social expectations can hinder sexual activity. "Women particularly are vulnerable to these ideas," Katchadourian said.

While the pairing of an older man with a young woman is considered acceptable, even enviable, the pairing of an older woman with a young man is not, he said.

What can one do? "The best way to preserve sexual vigor is sex itself," Katchadourian said. Physical changes that occur with menopause are less drastic in those women who remain sexually active.

"It's like saving money," he said. "You've got to start early in life."

STANFORD—

Stanford University School of Medicine and the American Red Cross are working to iron out differences stemming from Stanford's decision to develop its own blood bank, Dr. Lawrence G. Crowley, acting vice president and dean, said Wednesday, November 21.

He issued the statement in response to an article in today's edition of the *Stanford Daily* reporting a rift in Stanford-Red Cross relationships.

The article quoted Dr. Donald Avoy, medical director of San Jose Red Cross, that his organization would file suit for breach of contract unless a new agreement to supply the university and recruit donors in the area was reached soon.

According to Robert Rosenzweig, vice president for public affairs, the policy of the university is to allow blood donor recruitment on campus for all blood banks, as long as they coordinate their drives with the University's blood donor drive coordinator.

The purpose of this policy is to establish not only better communication between local blood banks and the Stanford community, but to assure that the University's own blood bank and its needs are met, he added.

A year ago the University announced its intention to develop its own blood bank located near the Stanford University Medical Center.

The move, the University said, was necessary because of the patient needs of the Stanford University Hospital and academic program needs of the Medical School.

Prior to that Stanford's blood needs were served by a combined effort with the Central Regional Red Cross Blood Services, and located on 3330 Hillview Avenue in the Stanford industrial park.

The present contract with Red Cross expires December 31.

Crowley explained that the Hospital and Medical School have had long-established programs in transplantation, treatment of leukemia, and disorders of the immune system in which the faculty has pioneered new treatments.

"It was determined," Crowley said, "that Stanford, operating its own blood bank and developing certain blood products essential for patient care and academic research in the area of immunogenetics and immunohematology, was essential."

-more-

He noted the University trustees have approved the academic program for the blood bank recently, and have allocated $1.6 million to finance the remodeling of the Redwood Building, 800 Welch Road, which the University has leased for the relocation.

The relocation includes a marked upgrading of research laboratory space, and a greater effort on the part of personnel in the recruitment of donors and processing of blood.

In addition, Crowley said, the closeness of the blood bank to the hospital should also improve patient care by reducing delivery time of specialized blood products.

Initially, Crowley explained, this move was undertaken with the cooperation of the Red Cross which later raised objections to a number of items. These ranged from recruitment of donors to Stanford's working with the Peninsula Blood Bank which supplies part of Stanford Hospital's needs.

At the heart of the dispute, Crowley said, is the philosophy of two different systems of blood banking.

These two systems are of equal quality, but differ in a fundamental way. Peninsula Blood Bank and its affiliates in the American Association of Blood Banks have traditionally argued for the use of a non-replacement or penalty fee as a way of recruiting donors. The Red Cross believes that giving blood is a community responsibility.

"The problem, however, facing Stanford is that it is located in the border zone, right on the edge of the two blood banking philosophies."

Many citizens, he said, who donate blood have their preferences too. There are those, particularly many employees of companies in the Stanford industrial park, who will not donate blood to the Red Cross because it will not give credits.

And there are those who feel, like the Red Cross, that giving blood is everybody's responsibility and should be done without credit.

"If some people won't give blood without credits, it's their business," Crowley said. "And as long as this system is legal Stanford has no right to eliminate a large group of donors who prefer other blood banking systems."

"Our position is to proceed with the development of a Stanford Blood Bank while continuing our discussions to develop a working arrangement for the participation of Red Cross in our program, Crowley said.

STANFORD—

Problems of aging, including sleep disorders, sexuality, and memory loss, will be the subjects of a free public program at Stanford University School of Medicine Thursday evening, November 29.

The program will be held at 8:00 p.m. in the Medical School's Fairchild Auditorium. It is being sponsored by the Friends of Psychiatry and Behavioral Sciences, a public information and fund raising organization associated with the Medical School.

Speakers include Drs. William C. Dement, director of the Stanford University Sleep Disorders Clinic and Research Center, Herant A. Katchadourian, author of the book *Human Sexuality: Sense and Nonsense,* and Jerome A. Yesavage, a geriatric psychiatrist conducting research on memory loss.

Dement, professor of psychiatry, is an internationally-known authority on sleep disorders, and currently is serving as president of the American Association of Sleep Disorders Centers.

Research at the Stanford center includes studies of the effectiveness of sleeping pills, sleep apnea, or cessation of breathing during sleep, and the use of chronotherapy (manipulations of the natural day-night rhythms of the body) to treat insomnia.

Dement is author of the book *Some Must Watch While Some Must Sleep.*

Katchadourian is professor of psychiatry, and Stanford University vice-provost and dean of undergraduate studies.

He originated and teaches "Human Sexuality," the most popular undergraduate course at the University in terms of enrollment.

Recently, he has focused on problems of sexuality during middle and older age.

Yesavage is assistant profesor of psychiatry at Stanford, and director of the psychiatric intensive care unit at the Palo Alto Veterans Administration Medical Center.

Currently, he and his colleagues at the VA are testing pharmacological and psychological treatments of dementia, a syndrome characterized by loss of memory, in the elderly.

City Desks: The following story on how Stanford University Hospital is coping with costs is included as a sidebar to Dr. Philip Lee's commentary on costs mailed simultaneously.

STANFORD—

How is Stanford University Hospital attempting to deal with rising costs?

According to Dr. James B.D. Mark, professor of surgery and chairman of a new medical staff committee on voluntary cost containment, the answer is to educate the physician.

"Doctors have a tremendous amount of leverage on the total cost of doing medical business," Mark said.

The committee's first project is a pocket-sized guide listing hospital charges for services that are ordered by physicians.

Called the "Physician Pocket Guide to Hospital Costs," it includes the current prices for various laboratory tests, x rays, electrocardiograms, medications, antibiotic therapy, operating room time, and room rates.

"The idea," Mark said, "is to make physicians aware of costs, so that they can assess benefits in relation to costs."

The committee also is considering other ways of informing physicians about costs, such as sending copies of the hospital bills of a certain percentage of patients to their attending physicians.

In the Stanford University School of Medicine Drs. Peter Rudd and Keith Marton, both assistant professors of medicine, are bringing cost considerations into the early training of physicians.

They have put together a packet of cost information and articles being used in the course "Introduction to Clinical Methods," taught to preclinical students. Versions of this packet will be developed later for clinical students and interns and residents.

Although doctor fees make up only 21 percent of the total personal health care expenditures, recent studies show that doctors control as much as 91 percent of the expenditures for hospital services because of their role as prime decision makers.

And as Mark put it, "increasing expenditures do not necessarily increase quality of care."

The hospital's pocket guide to costs has been well received by the medical staff as judged by the number of requests for copies, officials reported.

STANFORD—

Common laboratory tests and x rays contribute more to high medical care costs than brain scanners and coronary bypass surgery, a University of California professor said Friday, November 16.

Along with inflation and changes in the complexity of care, it is probably the "nickle and dime" technologies rather than the "big ticket" items that are driving costs up rapidly, especially in hospitals, Dr. Philip Lee said.

Brain scanners have drawn particular attention because they are expensive and highly visible, but most of the costs are elsewhere, he said.

Lee is director of the UC Health Policy Center in San Francisco. He spoke in Palo Alto at the Big Game Medical Alumni Reunion of the Stanford University School of Medicine.

He stressed that fee-for-service, the most common method of paying physicians, encourages them to use medical technologies.

In the past 30 years, he said, the average number of laboratory tests on a patient with a perforated appendix rose from 5.3 to 31. For maternity care, the number of tests rose from 4.8 to 13.5. And the average number of electrocardiograms per patient rose from 5.4 in 1964 to 9 in 1971.

Citing various studies, Lee estimated that the cost for outpatient laboratory tests and x rays reached about $6.7 billion in 1975. A newer study places the price tag for radiologic procedures alone to more than $7 billion in 1978.

"The use of laboratory tests and radiologic procedures is intimately tied to physician behavior and method of payment," he said. "In my judgment it's closely linked to the present policies of insurance companies and Medicare and Medicaid."

About 130 million people in the United States are covered by health insurance policies paying doctors fee-for-service, or the so-called "usual, customary and reasonable charge system."

" This system essentially allows physicians to set their own level of reimbursement," Lee said.

When the government imposes controls on fee schedules to curtail prices, doctors offset their losses of income by increasing the number of their services, he said.

The medical profession, Lee said, is challenged more than ever to examine its own role and consider alternatives to the present "cherished fee-for-service system."

-more-

If the profession fails to initiate changes, federal controls will be inevitable, he said.

Lee said doctor fees make up only 21 percent of the total personal health care expenditures. But the physicians's role as the primary decision-maker regarding utilization of health services has been grossly underestimated.

Doctors control as much as 91 percent of the expenditures for hospital services, and 76 percent of expenditures for the physician services," he said.

Lee said that when treatments change because of new drugs or techniques the costs rise more rapidly than if the treatments had remained unchanged. Increases in costs are correlated with a dramatic rise in the number of laboratory procedures, x rays, and use of prescription drugs.

"The problem, however, is not simply one of overutilization," Lee said. A Harvard study found that excessive use of radiologic procedures embodies excessive radiation per film, excessive films per examination, and excessive examinations per patient.

The latter was found related to a number of factors, Lee noted. They include a lack of knowledge by doctors of the capacities and limitations of x rays, undue dependence on them rather than clinical followup, patient demand, hospital policies, defensive medicine, and reimbursement method.

Lee said prescription drug use also increased dramatically in the past 30 years. The average number of prescriptions dispensed by pharmacies and physicians rose from 2.4 per person per year to 6.9 in 1976. The total number of prescriptions increased from 303 million in 1950 to 1.5 billion today.

"The benefits in some cases have been spectacular," Lee said. "In other cases the seriousness of adverse drug reactions, improper use or irrational prescribing have marred the benefits."

"One question that must be asked with respect to the use of technology--radiologic tests, prescription drugs, medical devices, surgical procedures--is whether or not the technology is used rationally or appropriately," he said.

Another aspect is to consider both the costs and benefits of medical services in the decision to produce them, Lee added.

STANFORD—

Dr. Donald Laub, chief of the division of plastic and reconstructive surgery at Stanford University School of Medicine, has resigned his faculty positions to join the Palo Alto Medical Clinic.

Laub's resignation, both as chief of the division and as associate professor of surgery, becomes effective January 1, 1980.

Laub will join the department of plastic surgery at the Palo Alto Medical Clinic. He will remain on the medical staff of Stanford University Hospital, and will continue to teach resident physicians as a member of the Medical School's clinical faculty.

"We are sorry to see Dr. Laub leave the faculty," said Dr. John A. Collins, chairman of the department of surgery at Stanford. "He is an excellent teacher who has done a fine job in creating a first-class training program in plastic and reconstructive surgery."

Laub, 44, has been a member of the Stanford faculty for 13 years, and has been chief of the division of plastic and reconstructive surgery since 1967.

He is well known as the founder and president of Interplast, Inc., a private organization of physicians who provide free medical care to people in Latin America, and the South Pacific.

In addition, Laub has directed the Gender Dysphoria Program at Stanford for the past several years. The program provided psychological counseling, and hormonal and surgical treatment of the condition commonly known as transsexuality.

Laub said his care of patients with gender dysphoria will continue, as will his involvement in Interplast.

A 1960 graduate of Marquette University Medical School in Milwaukee, Wisconsin, Laub received residency training at the Yale New Haven Medical Center and at Stanford.

He is active in several professional societies, and recently was elected president of the Educational Foundation of the American Society of Plastic and Reconstructive Surgeons. Among his awards is the Physician's Recognition Award by the American Medical Association.

In addition to his clinical and teaching activities, Laub has authored over 50 scientific publications.

Recent advances in the study of biological structures will be the focus of an international conference held at Stanford University School of Medicine November 19 and 20.

The conference, sponsored by the Stanford Magnetic Resonance Laboratory, will be held in the Medical School's Fairchild Auditorium and is open to the public.

The emphasis of the conference will be on the recent discoveries of molecular motions in macromolecules (large molecules like proteins and DNA), and in cell membranes, says Oleg Jardetzky, professor of pharmacology at Stanford and director of the Magnetic Resonance Laboratory.

Some of the new approaches that will be presented at the conference are described below:

Calvin Quate, professor and chairman of applied physics at Stanford, will discuss the acoustic microscope, a device he developed which enables scientists to see tiny objects by the use of sound waves.

Jardetzky and Michael Hogan, postdoctoral fellow in the Magnetic Resonance Laboratory, will discuss the use of nuclear magnetic resonance (NMR) to "map out" internal motions in proteins and DNA. NMR is a powerful method for the study of molecular properties.

The Stanford group has demonstrated that molecular motions in DNA are stopped by the binding of drugs.

The use of NMR to study the mechanisms of enzyme inhibition by drugs will be discussed by G. C. K. Roberts, senior member of the National Institute for Medical Research in London.

Patrick Cozzone, professor of biochemistry at the University of Marseille, and Steven Boxer, assistant professor of chemistry at Stanford, will discuss a new NMR technique using the laser to map out surfaces of macromolecules.

Harden McConnell, professor of chemistry at Stanford, will discuss laser imaging of motions in cell membranes; in particular, the study of interactions of synthetic cell membranes with the immune system.

The Magnetic Resonance Laboratory has sponsored the conference for the past five years. The Laboratory was established in 1972 under grants from the National Institutes of Health and the National Science Foundation. It serves as a national center for the study of molecular structure.

Engineers in Stanford Medical Center's Department of Facilities will vote Friday, Nov. 30, to decide whether to retain their unaffiliated labor organization, join an engineering local, or to have no union.

Approximately 90 engineers are eligible to cast ballots in the election, which will be supervised by representatives of the National Labor Relations Board (NLRB).

Polling stations will be set up at the main medical center and at Hoover Pavilion, which is also a part of Stanford University Hospital. Balloting Nov. 30 will be from 7 to 9 a.m. and 3 to 5 p.m.

The engineers currently have their own unaffiliated labor organization known as SUMCEDA, which is an acronym for Stanford University Medical Center Engineering Department Association.

The engineers will decide whether to retain SUMCEDA, to join Local 39 of the Operating Engineers, AFL-CIO, or to have no union at all.

According to Ross Campbell, associate counsel at Stanford Medical Center, a runoff election would be held at a later date in the event none of the three ballot choices receives 50 percent of the vote.

"Four Hundred Years of Wound Healing" will be the subject of the third annual Charles and Gertie Thuss Lecture held at the Stanford University School of Medicine on Thursday, November 15.

Dr. Fernando Ortiz-Monasterio, professor of plastic and reconstructive surgery at the National University of Mexico, will deliver the lecture at 4:00 p.m. in Room M106.

Members of the medical community and the public are invited to attend. The lecture is sponsored by the Medical School's division of plastic and reconstructive surgery.

Dr. Ortiz-Monasterio is well known for his methods of correcting cleft lip nasal deformities and other craniofacial anomalies. He served as chairman of the Department of Surgery at the Hospital General de Mexico, and currently is that institution's chief of plastic surgery.

A graduate of the University of Mexico School of Medicine (1945), Ortiz-Monasterio has authored numerous publications, and is active in many professional organizations including the American Society of Plastic Surgeons.

The lectureship was established in 1977 by Dr. Charles J. Thuss, Jr., who is associated with South Texas Pathology Associates in San Antonio, Texas, and Mrs. Thuss, a member of the Stanford class of 1966.

It honors his late parents, Dr. Charles J. Thuss, Sr., and Gertrude Noble Thuss, a former registered nurse. Dr. Thuss practiced plastic surgery at Kaiser Hospital in Santa Clara, and was clinical associate professor of surgery at Stanford Hospital.

STANFORD—

New technology, and better understanding of biomechanics and physiology have improved the diagnosis and treatment of sports-related injuries.

These advances have benefitted not only the professional athlete, but the recreational jogger as well, according to two sports medicine specialists at Stanford University Medical School.

Drs. K. Gordon Campbell, clinical associate professor of surgery, and Michael F. Dillingham, director of the Sports Medicine Clinic in the Medical School's division of orthopedics, described the types of injuries commonly suffered "on the playing fields," Tuesday evening, November 13, at the Law School's Kresge Auditorium.

Their talk was the third in a series of three lectures on sports medicine sponsored by the Medical School and the Medical Center Council.

According to Dillingham, one of the real advances in orthopedic diagnosis was the development of the orthoscope. This device is a tiny "telescope" which enables doctors to look directly inside joints for injuries.

"The orthoscope has taken the guess work out of diagnosis," Dillingham said. It is particularly useful in diagnosing injuries in children.

It is commonly believed that children are so flexible they can't hurt themselves, and that their "growing pains" are no cause for concern.

On the contrary, Dillingham said, injury to growing bones and tissues can occur, and can lead to improper growth rates and deformity. In addition, "children do not rehabilitate well against pain," he said. "If their knees hurt, they simply will not exercise, and their joints will become stiff."

The orthoscope can accurately determine if the injuries require surgical correction, he said.

Other diagnostic tools include bone scanning, CT (computerized tomographic) scanning, and gait analysis. The bone scan involves injection of radioactive isotopes into the body, which accumulate in areas of increased metabolism, indicating injury. The bone scan can detect injuries which are invisible in X rays.

- more -

Gait analysis involves the use of lights or electrodes to study the range of motion of injured limbs, and to determine neurological handicaps.

Campbell, who also is the team physician of the San Francisco Giants, said that new treatments are used in professional athletes to speed recovery of their injuries.

Athletes with tendonitis, or inflamed tendons, for example, may be given whirpool treatments, ultrasound, heat, and electrogalvanic stimulation several times a day "to shock the tissues and help turn off inflammation."

However, most people don't need special treatments even if they could afford them, Campbell said.

For sprains, use common sense, he said. Rest the injured joint, elevate it, and place a pack of ice on it to reduce swelling.

In addition, simple "preventive maintenance" can reduce the likelihood of injuries occurring in the first place.

For runners, this means exercise and stretching before heading out to the track, wearing the right kinds of shoes, and running on soft surfaces whenever possible.

Many people suffer chronic muscle fatigue, sprains, and even fractures when they run because their arches may be too flat or too elevated, or their knees and ankles may be "out of alignment."

Orthotics often can help these people, Dillingham said. Orthotics is the use of wedges or other supports to place joints in a neutral position and remove the stress from other parts of the body. "The idea is not to correct the adult part, but to accommodate what Mother Nature has given it," he said.

Occasionally, exercise and orthotics cannot relieve the problems, and surgical correction may be necessary.

Most important to athletes, professional or otherwise, Campbell said, is that they do not disregard warning signs of injury. A simple wrist sprain may actually be a broken wrist bone. If unattended, it could lead to arthritis. "Listen to what your body says," he added.

STANFORD—

Heredity, weight gain, obesity, and lack of physical activity significantly increase the risk of developing high blood pressure according to Stanford University epidemiologist Dr. Ralph S. Paffenbarger.

In a study of nearly 15,000 Harvard University alumni aged 35 to 74, Paffenbarger and his colleagues Alvin L. Wing, Robert T. Hyde, and Dexter L. Jung, have correlated incidence of high blood pressure with each of these factors.

They found that men who did not participate in vigorous exercise such as swimming, running or tennis, were at 35 percent higher risk of developing high blood pressure than those who did, and the protection of vigorous sports was particularly notable among overweight men.

The researchers also discovered that men who were 20 percent heavier than their ideal weight (according to height) were at 78 percent greater risk of getting high blood pressure than leaner men.

Alumni who had gained 25 pounds or more since entering college were at 60 percent greater risk than those who gained less weight, the researchers found.

In addtion, men whose parents had high blood pressure showed 83 percent higher risk of getting the disease than men whose parents had no such medical problem, the study showed.

Paffenbarger says that these results are important because high blood pressure is itself a strong indication of heart attack risk.

Family tendency seems the most clinically significant risk characteristic, says Paffenbarger, but lack of participation in vigorous sports represents a strong overall risk in the population because so few individuals engage in vigorous exercise.

Parental history of high blood pressure is the only risk factor that could not be reduced through the individual's own efforts, Paffenbarger noted.

Information was obtained through mailed questionnaires filled out in 1962, 1966 and 1972. During the six to ten year period of study, 681 of the participants developed high blood pressure.

The researchers compared information on those who developed the condition with those who did not in order to calculate the relative risk contributed by each factor.

Paffenbarger presented the study results at a meeting of the Americn Heart Association in Anaheim Tuesday, November 13.

A memorial service will be held Friday (Nov. 16) in Connecticut for a Stanford Medical Center registered nurse who died along with four others while on a volunteer medical flight in Mexico.

Jo Hebard and her four companions were part of the Flying Doctors medical team of Northern California. All died instantly when their Cessna 210 crashed into trees in the rural Mexican town of Movas last Friday.

Hebard, whose father George W. Hebard is a practicing physician in New Canaan, Conn., had worked the past four years as a nurse practitioner in the DES (subspecialty) Clinic in Gynecology-Obstetrics at Stanford.

The DES Clinic examines women whose mothers took the synthetic estrogen compound diethylstilbestrol during pregnancy. DES exposure has been associated with a rare form of vaginal cancer and, more commonly, with non-malignant changes in reproductive organs.

The group of five, which included two dentists, was making a regularly scheduled medical mission to remote areas of Mexico. Six other airplanes carrying other members of the Flying Doctors were also in Mexico last week as part of their monthly medical mission.

Hebard's memorial service Friday will be in the New Canaan Presbyterian Church. Details are not yet complete, but internment will also be in New Canaan.

In lieu of flowers the family requests contributions be sent to Skidmore Nursing School in Saratoga Springs, N.Y. 12866.

STANFORD—

Stanford University has been awarded a $193,000 grant by the National Center for Health Services Research to analyze new technology used in the treatment of rheumatic diseases such as arthritis.

The study will follow the medical histories of 2,000 patients with arthritis at several institutions in the U.S. and Canada, using the American Rheumatism Association Medical Information System (ARAMIS), a national data bank based at Stanford Medical School.

"We hope to bridge the gap between the laboratory and the community," says study director Dr. James Fries, associate professor of medicine at the Medical School.

Fries says that new technologies and treatments often do not work as well in the community as they did under laboratory conditions.

"This may be due to the fact that patients are selected for initial clinical trials because they are not likely to have complications, or suffer side-effects from the treatments," he says. "This practice makes trials more ethical, but less representative of the world outside the teaching hospital."

Fries says the study will determine the benefits of new drugs and diagnostic tests in community settings. The researchers also will test reliability of laboratory tests performed at different institutions, and will track down possible side-effects of new drugs, by surveying the patient population.

In addition to Stanford, study participants include University of California at San Francisco, the University of Cincinnati, the University of Saskatchewan, the University of Pittsburgh, and the Phoenix Arthritis Center.

STANFORD—

The role and responsibility of physicians in determining the cost of medical care will be the topic of the featured address by Dr. Philip Lee at the Big Game Medical Alumni Meeting at Stanford University School of Medicine on Friday, November 16.

Lee is professor of social medicine and director of the Health Policy Program at the University of California in San Francisco. He will present his remarks following a lunchtime reception for alumni, associates, faculty and spouses at the Holiday Inn in Palo Alto.

During the morning clinical symposium in Fairchild Auditorium on campus, three speakers from Stanford medical school will discuss recent advances in diagnosis and treatment of heart conditions.

Dr. Michael Goris, assistant professor of radiology, will talk about four promising diagnostic procedures now available using radionuclide imaging of the heart.

Ultrasonic sector scanning of the heart, a new method of defining heart anatomy and identifying certain heart defects and diseases, will be discussed by Dr. Richard Popp, associate professor of medicine.

Dr. Bruce Reitz, assistant professor of cardiovascular surgery, will describe methods for surgically correcting certain complex abnormalities of the heart in infants.

A ceremonial planting of a plane tree on Alumni Green will kick off the daylong program of activities.

The tree is a descendant of the plane tree under which Hippocrates taught medicine on the Island of Kos in the fifth century, B.C., and was recently given to the medical school by the people of Greece. The tree will be presented by Dr. John Sarracino, associate chief of pediatrics at East Valley Medical Clinic in San Jose.

The Big Game Medical Alumni Meeting is an annual event presented by the Stanford Medical Alumni Association and the medical school's Office of Postgraduate Medical Education.

FOR IMMEDIATE RELEASE

STANFORD—

A new program to train future doctors in the care of old people and diseases of aging will be launched by the department of family, community and preventive medicine of the Stanford University School of Medicine.

Funded by a $300,000 grant from the National Institute of Aging for the next three years, the program will stress the team approach to geriatrics, and will cover in depth issues in the training of physicians.

The program will be directed by Dr. Moira Fordyce, clinical associate professor. She will also coordinate development of the geriatrics curriculum.

An increasing proportion of the population is elderly, and all medical students will treat old patients sometime later in their careers, says Fordyce.

The goal of the new curriculum, she adds, is to provide students with wide knowledge of both normal and abnormal aging processes and the physical, psychological, social, economic and epidemiological aspects to growing old.

"We will stress the team approach to geriatrics, which involves physicians in specialized areas of medicine and family practice as well as nurses, social workers, physicians' assistants, physical therapists and other health professionals," notes Fordyce.

Students often become frightened of elderly patients through lack of exposure in medical school and through exposure to the chronically sick old in unfavorable settings, observes Fordyce.

In addition, students may become intimidated because the elderly have numerous problems ranging from medical to social, economic and emotional ones, she adds.

"What we would like to stress to students is that they need not solve all problems of the elderly single-handedly. A team can be made available who can help with many of these troubles. Merely because doctors often identify these problems does not mean they have to solve them all," Fordyce explains.

"We also plan to emphasize preventive medicine and the community resources available for keeping the elderly healthy and at home," she adds.

Prior to her arrival at Stanford, Fordyce was director of geriatrics at Texas Tech University School of Medicine.

She received her medical training at Glasgow University School of Medicine and worked with Sir William Ferguson Anderson for a year in acute and chronic geriatrics.

In Scotland, geriatrics has been taught as a required course in medical schools for many years, she says, and the team approach to problems of the elderly in the hospital and in the community is practiced everywhere in medicine in Britain.

STANFORD—The third and final autumn Progress in Medicine Lecture on Sports Medicine presented by Stanford Medical School will be given Tuesday, Nov. 13, at Stanford University's Kresge Auditorium starting at 7:30 p.m. The lecture is free and open to the public.

Drs. K. Gordon Campbell and Michael Dillingham will discuss "On the Playing Field," a review of contact sports, racquet games and running.

Campbell is clinical associate professor of surgery at Stanford and an orthopedic surgeon in the Department of Sports Medicine at Palo Alto Medical Clinic. He is also team physician to the San Francisco Giants professional baseball club.

A native of San Francisco, Campbell earned his A.B. degree (1951) and his M.D. (1955) from Stanford. Prior to joining Palo Alto Medical Clinic he was a general surgery resident at New York-Cornell Medical Center.

Dillingham is director of the Sports Medicine Clinic of the Division of Orthopedics. He has been a resident in Orthopedic Surgery at Stanford and a fellow in the Spinal Cord Injury Unit at Santa Clara Valley Medical Center in San Jose, which is affiliated with Stanford.

Dillingham received both his A.B. degree (1966) and his M.D. (1971) from Stanford, and served his internship at Stanford.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of Stanford Medical School and by the Stanford Medical Center Council.

STANFORD—A promising new technique for "dissecting the immune system" is being applied to improve diagnosis and treatment of a wide variety of diseases, from leukemia to Legionnaire's disease.

The technique uses highly specific antibodies, microscopic molecules which often form the body's first line of defense against germs and other foreign invaders.

Called monoclonal antibodies, because they are made by cells descended from a single cell (clones), these molecules have provided scientists with a powerful tool, a pure chemical reagent which can be applied to basic research in cellular biology as well as clinical medicine.

"Monoclonal antibodies provide a marvelous set of tools for fundamental research," said Dr. Leonard Herzenberg, professor of genetics at Stanford University Medical School.

"But they also will allow the therapy for cancers to be tailor-made."

Herzenberg discussed the use and applications of monoclonal antibodies November 8, at a meeting of the Council for the Advancement of Science Writing in Palo Alto, CA.

Currently, 50 percent of childhood leukemias can be cured, Herzenberg said. But "why can't we cure the rest?"

It's because there are different types of leukemia, just as there are different types of white blood cells, from which the tumors are derived, and "we can't tell them apart at the moment," he said.

However, with the use of monoclonal antibodies, different cell types can be identified, and treated accordingly. When physicians are able to tailor make therapy to the individual patients and their cancers, "we have a real chance of beating all of childhood leukemia," Herzenberg said.

Similarly, monoclonal antibodies can be used to screen for external agents, like the bacterium that causes Legionnaire's disease.

"This was an unknown disease until a few years ago," Herzenberg said. "We still don't know where these bacteria are hiding, but they are hiding in the environment around us, probably in the soil."

Now, a specific antibody has been identified which reacts with the bacterium. It can be used to diagnose Legionnaire's disease in patients, and even to screen soil or the water in air conditioning systems for the bacterium, he said.

Other potential applications of monoclonal antibodies include:

- furthering understanding of disease such as arthritis, multiple sclerosis, and disbetes,
- speeding prenatal diagnosis of genetic disorders, and
- aiding tissue typing for organ transplants.

Monoclonal antibodies were first produced in 1975 by Dr. Cesar Milstein, of the Medical Research Council in Cambridge, England, and Dr. Georges Kohler, now in Basel, Switzerland.

The researchers were trying to produce new antibody molecules, by fusing mouse spleen cells with mouse myeloma (bone marrow cancer) cells, and growing them in culture.

What they got was a hybrid cell, called hybridoma, which has some of the features of the spleen cell (producing antibodies), and some of the features of the tumor cell (rapid and continuous growth).

-more-

A spleen cell producing a pure antibody is thus "immortalized," Herzenberg said. It will continue to produce a specific antibody, and only that antibody, for years.

Herzenberg studied with Milstein in 1976, and that year brought the technique to Stanford. He and his colleagues have been able to speed production of antibody-producing clones with the fluorescence-activated cell sorter, a space-age research tool they developed in 1971.

First, rats are given injections of mouse cells. The rat spleen cells then produce a battery of antibodies against different mouse cell markers, called antigens, which they recognize as foreign.

The spleen cells are harvested, and fused with myeloma cells. Later, the fused cells are mixed with tiny, fluorescent plastic beads, coated with a certain mouse cell marker.

Those cells which produce antibody against this marker bind the beads.

The solution of cells is passed in a stream through the cell sorter. A laser beam directed at the stream lights up cells carrying the fluorescent tag. This sets off high voltage pulses which kick the fluorescent cells out of the stream and into rows of culture plates.

In this way, the researchers can quickly isolate hybrid cells producing antibody against a single, preselected cell marker.

"This is a big time saver," Herzenberg said. Other techniques required that the specific antibody-producing cells, often at concentrations of one cell per 10,000, be purified laboriously by growing all the cells in culture. "With the cell sorter, we can pull out 100 of the cells we want in two minutes," he said.

"this technique is superb. We are making rapid progress."

One of Herzenberg's current projects is in the field of prenatal diagnosis. Using monoclonal antibodies produced by researchers at Harvard and Oxford Universities, he and his colleagues have been able to detect fetal cells in the mother's blood as early as 15 weeks after conception. They are now trying to produce monoclonal antibodies against specific fetal cell markers, in order to isolate the cells more easily from the maternal serum.

If they can isolate the cells, grow them, and study their chromosomes, they will have a simple, safe and inexpensive test for detecting genetic defects, which can be performed at an earlier time in gestation than is now possible.

Herzenberg said that monoclonal antibodies may one day be regarded as a commercial product, "a standardized, reproducible, pure chemical reagent, which can be passed between labs and hospitals."

For example, genetic counseling centers in hospitals could obtain monoclonal antibodies to speed prenatal diagnosis of genetic disorders. Organ banks could use them to improve tissue typing of organs and body parts for transplantation. And epidemiologists could apply it to the study of disease among populations, and the evolution of new strains of viruses.

All these applications would be facilitated by industrial production and distribution of monoclonal antibodies, Herzenberg said.

Herzenberg has passed on some of his cell lines to other noncommercial investigators through the Jonas Salk Institute in San Diego. At the same time, Stanford University is exploring the issuing of licenses to companies interested in producing and selling antibodies from Stanford clones.

STANFORD—

Advances in research on schistosomiasis have recently been made at Stanford University, shedding light on a disease that afflicts about one in 15 people worldwide.

With no known means of prophylaxis and no ideal drug to combat the parasitic disease, it is spreading rapidly, particularly in developing countries, according to Dr. Paul Basch, associate professor at Stanford University School of Medicine.

Basch, one of a small number of researchers in the United States to study the parasitic worm that causes the disease, is developing successful techniques for growing the worm by itself in the laboratory.

Until now, the only practical method of growing the organism has been in animals, where the worms can't be seen or studied directly. For this reason, little is known about their nutrition, or how they mature, find a mate, and produce eggs. Such knowledge would help to interrupt its life cycle and gain some control of the disease, Basch says.

Schistosomiasis is one of six major tropical diseases targeted for research by the World Health Organization. Despite their impact on a global scale, with high death rates, illness and economic loss, relatively scant research on tropical diseases is carried out in this country, notes Basch.

Improved sanitation in developing countries is the key to interrupting the spread of schistosomiasis, but economic conditions perpetuate the disease, Basch explains.

If the worm can be intensively studied in the laboratory, other methods may be discovered for gaining control over its spread, he contends.

The parasite requires two hosts—man (or less frequently, another mammal) and certain fresh water snails.

People acquire the infection from water contaminated with infective larvae released from snails. These microscopic larvae penetrate unbroken skin and eventually grow to mature, mate and produce eggs in the person's blood.

- more -

By means of irritating secretions, many eggs erode through blood vessels and the intestinal wall and pass out of the body in the feces. Organisms hatching from these eggs can enter snails, where they multiply to produce thousands of the infective larvae that may reinfect humans, repeating the life cycle.

The severe illness caused by the worms is due to the many eggs that enter the liver, becoming physically trapped there instead of passing out of the body, Basch says.

These eggs irritate surrounding tissue which forms a fibrous capsule in response to the foreign body. Large portions of the liver may become fibrous, imparing its function, he explains, and creating the characteristic "big belly."

Blood circulation is also obstructed and veins may rupture, leading to severe or fatal bleeding, Basch adds.

Population growth, crowded conditions and unsanitary waste disposal all contribute to the spread, he notes. Irrigation projects and hydroelectric dams are also providing wider habitats for snails.

Methods of snail control such as poisoning, release of predators, and filling in swamps and ditches, have achieved only marginal effects, Basch adds.

The People's Republic of China has for years had a program of control involving elimination of snails, case treatment and improved sanitation. Other countries, including Brazil and many parts of Africa are also struggling to combat this disease.

Basch's work is supported by the tropical disease program of the World Health Organization and by a grant from the Edna McConnell Clark Foundation of New York.

STANFORD—Medicare has announced that it will pay for some of the costs associated with heart transplantation at Stanford University Medical Center, at least until it makes a formal decision on covering the procedure.

The announcement was made Friday, November 2, in the form of a telegram to the Oakland, California office of Blue Cross, authorizing it to begin paying Medicare claims presented by Stanford for heart transplantation services.

Blue Cross acts as the intermediary for Medicare in California.

In the telegram, Leonard D. Schaeffer, head of the Health Care Financing Administration (Health, Education and Welfare Department) stated that the Public Health Service will make a formal opinion on the medical necessity of cardiac transplantation by January 1, 1980, and that the government will make the final decision on coverage "as soon thereafter as possible."

"We are gratified by the thoughtful action of the government in providing Medicare coverage to those patients who are in need of transplantation during this period of review," said Dr. Edward Stinson, head of the transplant team at Stanford.

"The life expectancy of patients accepted as potential transplant recipients is less than six months, and it is simply not possible for the hospital to help all of them without insurance coverage.

"We are hopeful that the final decision will be in favor of covering the procedure," said Stinson.

Heart transplantation at Stanford can cost over $100,000 for some patients.

In the past, the costs have been met through private resources, insurance coverage, and portions of a government grant provided to Stanford.

The costs of heart transplantation never have been covered officially by Medicare. However, it has paid for selected aspects of the care of 37 patients out of a total of 103 transplanted at Stanford from December 1973 to May 1979.

The 37 patients qualified for Medicare coverage because they were totally and permanently disabled by their heart disease.

- more -

However, in May 1979, Medicare notified Stanford that it would no longer pay for heart transplants while it determined whether to cover the procedure.

As a result, other sources of support, including the government grant, were committed more quickly than usual, and it became more difficult for Stanford to evaluate as many patients for possible transplantation as it has in the past.

On September 17, Dr. Norman Shumway and members of the heart transplant team at Stanford sent a letter to the Health Care Financing Administration (HCFA), urging the government to officially approve coverage of the procedure.

Included with the letter were several papers and other data on the Stanford program.

According to Schaeffer, this data has been reviewed by the National Heart, Lung and Blood Institute (part of the National Institutes of Health), which found:

• while patients selected for transplantation at Stanford have an average life expectancy of less than six months if untreated, their five-year survival rate after cardiac transplantation is 50 percent.

• Dr. Shumway carefully screens all patients for cardiac transplantation to insure optimum chances for survival.

• the provider, Stanford Medical Center, is properly equipped and staffed to perform cardiac transplantation in a safe and effective manner.

"On the basis of these preliminary findings," Schaeffer stated in the telegram to Blue Cross, "HCFA has tentatively concluded that the transplant procedures performed at the Stanford Medical Center meet the criteria for medical necessity."

STANFORD—

The first successful recording of electrical signals from inside human epileptic nerve cells was reported today by Dr. David A. Prince, chairman of the Department of Neurology at Stanford University and his associate Dr. Robert Wong, at the ninth annual meeting of the Society for Neuroscience in Atlanta, Georgia.

Their experiments were done using new techniques for keeping brain slices alive in an artifical laboratory environment.

Using glass probes, called microelectrodes, whose tips measure less than 1/25000 inch in diameter, the Stanford team recorded signals from normal nerve cells and those from small pieces of brain removed by neurosurgeons as part of the treatment for patients with epilepsy.

According to Prince, there are marked similarities between the electrical discharges in some nerve cells from epileptic brain slices and those known to occur in various animal models of epilepsy.

Nerve cells involved in epilepsy tend to fire bursts of repetitive impulses and this behavior is part of the excessive discharge pattern that may lead to seizures.

These results are important, Prince noted, because they point out that abnormalities of human epileptic neurons may be mimicked closely by those in animals, where more detailed studies can be done.

Prince and Wong also have shown for the first time that nerve cells in slices of epileptic brain tend to retain their abnormal behavior in an artificial environment.

"This will allow more detailed studies of the causes and potential treatments for epileptic discharges and will hopefully improve our understanding of human epilepsy," Prince said.

Epilepsy is one of the most common maladies a neurologist treats, affecting between two and four million Americans, Prince noted.

Prince's work is supported by the National Institutes of Health.

The vital and often complex role of operating room nurses will be highlighted on National Operating Room Nurses Day Wednesday, Nov. 14, at Stanford University Hospital.

A continual slide show and a medical-staff reception are part of the Stanford event, which is also being celebrated nationally following the signing of a proclamation by President Carter.

"There really is a big mystery about what we do," commented Gwenn Williams, director of Stanford Hospital's Operating Rooms. "We want to show the public who we are and what we do, and particularly to demonstrate the total nurse role concept we call 'perioperative nursing.' "

Williams says perioperative nursing is a "holistic approach to health care. It takes into account all the needs of our patients, and attempts to meet these needs through their entire hospital experience, including the preoperative and postoperative period."

There is a national trend toward this type of nursing care among operating room nurses, Williams noted.

The slide presentation is open to the public. It will be shown all day Nov. 14 in the hospital's first floor main lobby area.

(Editors: Williams and other Operating Room Personnel are available for interviews. Call Williams at 415: 497-5620).

STANFORD—

The special joys and health hazards connected with popular outdoor recreational sports, such as skin diving, climbing, skiing and scuba diving, will be examined in the next Progress in Medicine Lecture presented by Stanford Medical School on Tuesday, Nov. 6.

Speakers at the public lecture are Drs. Herbert N. Hultgren and Alfred P. Spivack. The talk begins at 7:30 p.m. in Kresge Auditorium at the university's law school.

Chief of the cardiology service at Veterans Administration Medical Center in Palo Alto, Hultgren is also professor of medicine at Stanford.

He has spent most of his professional career at Stanford, and is a Stanford graduate as well. He earned his M.D. from Stanford Medical School in 1943.

During 1955-67 Hultgren was chief of the Division of Cardology at the medical school. He is an avid mountaineer, skiier and tennis player.

Spivack is clinical professor of medicine and a consultant in electrocardiography at Stanford Hospital.

He is a former director of the hospital's Coronary Care Unit, and the hypertension clinic in the medical school.

A graduate of Temple University, Spivack received his M.D. in 1954 from Jefferson Medical College in Philadelphia, Pa. He was involved in research for the U.S. Navy Radiological Defense Laboratory prior to his appointment as a cardiology fellow at Stanford in 1959.

He is past president of the Santa Clara County Heart Association, and is a current member of the Undersea Medical Society, American College of Sports Medicine, a fellow in the American College of Physicians and a fellow in the American College of Cardiology.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of Stanford Medical School, and by the Medical Center Council.

The third and final lecture in the autumn sports medicine series will be given Tuesday, Nov. 13, by Drs. K. Gordon Campbell and Michael Dillingham. Their talk is entitled "On the Playing Fields," which will be a review of contact sports, racquet games and running.

STANFORD—

More than 100 science reporters and editors from newspapers and magazines in the United States and Canada will attend the week-long "New Horizons in Science 17th Annual Briefing" at Stanford University November 4 through 9.

Organized by the Council for the Advancement of Science Writing (CASW), the program will feature scientists reporting on the latest developments in their fields, from genetic predisposition to disease, to the awesome tangles unraveled by neuroscientists about the brain, to discoveries in high energy physics.

Other reports will cover energy risks, jumping genes, fancies of human evolution, weather prediction, quarks and the big bang, deep ocean hot springs, the social significance of dress, new dimensions and old illusions about psychic phenomena, gravity wave astronomy, and new archeological discoveries about the land of the Jews.

The sessions will be held in Rickey's Hyatt House Hotel in Palo Alto, and at Stanford Linear Accelerator Center.

A banquet, November 7 in the Stanford Faculty Club will feature the presentation of the National Association of Science Writers "Science-in-Society Journalism Awards."

The CASW is an independent, non-profit organization of science journalists. Through seminars and other educational programs, CASW has worked in the past seventeen years to improve the reporting of science in the daily press.

The program this year is supported by the National Science Foundation, Stanford University, and Stanford University Medical Center.

Speakers in this year's sessions are from the Atomic Energy Control Board of Canada; the California Institute of Technology, Pasadena; the University of California, Berkeley and Irvine; University of Chicago; IBM Thomas J. Watson Research Center, New York; Princeton University; University of Illinois, Urbana-Champaign; Scripps Institute of Oceanography, San Diego; Stanford Linear Accelerator Center, Stanford University, and School of Medicine.

STANFORD—

Physicians at Stanford University Medical Center today determined that Fred Kelley, the 39-year-old former fireman from Framingham, Massachusetts, does not meet the criteria for receiving a heart transplant.

While Kelley's heart condition renders him functionally disabled to continue working as a fireman, the Stanford doctors said it is not severe enough to warrant taking the risks associated with transplantation at this time.

However, they added, this does not rule Kelley out as a possible candidate in the future.

Kelley came to the Medical Center Monday, October 29 to begin tests to determine if he should receive a heart transplant.

He had been referred to Stanford by doctors in Massachusetts after he had suffered two heart attacks.

Cardiac transplantation as performed at Stanford is quite successful—70 percent of patients are still living one year after surgery, and nearly 50 percent are alive after five years. However, complications of the procedure include rejection of the transplanted heart by the body, and increased susceptibility to infection. In fact, infection is a major cause of death among transplant recipients.

Kelley was released from the hospital today, and will return home under the care of his doctor. However, if his condition worsens, he will be reevaluated at Stanford for possible transplantation, stated the Stanford physicians.

Mr. Kelley expressed his appreciation to the city of Framingham, whose board voted October 10 to increase the city's tax rate to provide the funds necessary for the evaluation. The $60,000 raised by the city will be held in escrow to be used in the future for reevaluation, Kelley said.

FOR FURTHER INFORMATION CONTACT: Bill Snyder 415: 497-6911

STANFORD—

Intracranial bleeding, a major cause of illness and death among premature infants, now can be diagnosed earlier and more accurately with a technique developed by Stanford University radiologists.

The physicians use ultrasound, a technique which bounces sound waves off internal body structures and constructs pictures of the echoes, to detect bleeding before clinical symptoms, such as seizures or cessation of breathing, occur.

Early detection of bleeding enables the physicians to monitor the infants for signs of increasing fluid in the brain, which often follows bleeding, and to treat the hydrocephalus, or swelling, before it causes damage.

The technique could help the estimated 40 to 70 percent of infants born prematurely and weighing under 1500 grams (3.3 pounds) in whom hemorrhaging (bleeding) occurs. Currently, about half of these infants die from the bleeding.

Dr. David London, resident physician in radiology at Stanford University School of Medicine, recently reported on the technique at a meeting of the Radiological Society of North America, in Atlanta.

London conducted the research under the guidance of Drs. Dieter Enzmann and Barbara Carroll, both assistant professors in the division of diagnostic radiology. The research was supported by the Department of Radiology.

The device adapted for premature infants originally was developed for use in the eye by Dr. Alan Susal, clinical assistant professor of ophthalmology, and engineers at the Stanford Integrated Circuits Laboratory.

The device directs a narrow ultrasound beam between the soft bones of the infants' skulls, toward the fluid-filled ventricles of the brain where the bleeding usually occurs.

Ultrasound can outline areas of bleeding as accurately as the conventional brain CT (computer tomographic) scan, said Enzmann in an interview.

However, ultrasound scanning can be done at the infant's incubator in the intensive care nursery more quickly than brain scanning, and can avoid the need to transport the critically ill infant to the brain scanning room.

In addition, ultrasound scanning avoids the risks of ionizing radiation. "There are no known harmful effects of ultrasound at the energy levels we use," Enzmann said.

- more -

Finally, ultrasound scanning is cheaper than CT scanning because the equipment is only about one-tenth the cost of CT scanners. Brain scanning, however, provides other, valuable information, particularly in ruling out the presence of other diseases, he said.

Enzmann said the exact cause of intracranial bleeding in the premature infants is not known. It occurs in a part of the brain which has disappeared in the normal term infant, indicating that the underdeveloped brain part is susceptible to hemorrhage under conditions of premature birth.

Statistics on the frequency of bleeding among premature infants are variable, Enzmann added, because only recently have physicians been able to detect the condition accurately with CT and ultrasound scanning.

In addition, as more infants survive other problems of prematurity, such as respiratory distress syndrome, "the next major hurdle they are likely to face is hemorrhaging," he said.

There is not much that can be done to treat intracranial bleeding in these tiny infants until it is known exactly when and under what conditions it occurs, Enzmann said.

However, once bleeding is detected, the infants can be monitored carefully by ultrasound for signs of brain ventricle swelling. This can be treated by lumbar puncture, to remove some of the fluid from the lower spinal cord and relieve pressure on the brain.

"Ideally, we'd like to scan every premature newborn infant in the intensive care nursery for signs of bleeding," he said.

In the future, the researchers plan a study to pinpoint when the hemorrhaging occcurs in these infants, and follow the sequence of events that leads to brain swelling.

In addition, they will monitor subsequent neurological and intellectual development in children who suffered intracranial bleeding, in conjunction with the Stanford Premature Research Center.

SCIENCE WRITERS: Release date for this story has been set to coincide with publication of the research report in *Proceedings of the National Academy of Sciences.* A press conference has been scheduled with Dr. Avram Goldstein Thursday, December 20 at 2 p.m. at the Addiction Research Foundation, 701 Welch Road, Palo Alto, Building B, 3rd floor. Please notify the News Bureau if you plan to attend. Texts of the scientific paper and photos are available on request.

ADVANCE FOR RELEASE IN AM PAPERS, FRIDAY, DECEMBER 21, 1979

PALO ALTO—

Scientists at the Addiction Research Foundation have discovered a new brain chemical, 200 times more potent than morphine, and 50 times more powerful than a previously identified chemical, beta-endorphin.

The substance is called dynorphin, from the Greek word for power (dynamis) and the word endorphin, meaning natural morphine. Dynorphin is a member of a family of brain peptides or small proteins scientists believe play a role in relieving pain and regulating behavior.

The discovery of the substance is significant because it is a step forward in understanding brain chemistry, and in particular, how Mother Nature regulates pain.

In addition, the high potency of dynorphin indicates that it binds with high specificity to its receptor, a special molecule that fits it like a lock fits a key.

Drugs or chemicals must interact with receptors in cell membranes in order to exert their effects.

It is not yet known where dynorphin acts in the brain, or what function it serves. But it may lead scientists to the discovery of a receptor, or lock, for some highly specific function, such as pain relief, and thus enable them to construct more selective and more powerful drugs which fulfill the function.

A report on the research was published Thursday, December 20 in the current issue of the *Proceedings of the National Academy of Sciences.* It was authored by Avram Goldstein, Shinro Tachibana, and Louise I. Lowney of the Addiction Research Foundation, and by Michael Hunkapiller and Leroy Hood, of the California Institute of Technology.

The Addiction Research Foundation is a nonprofit institution attempting to develop basic information and improve methods of treatment for addictive diseases.

Dr. Goldstein, director of the Addiction Research Foundation, is also professor of pharmacology at Stanford. Dr. Tachibana is a visiting scientist on leave from Eisai Ltd., a Japanese pharmaceutical firm. Mrs. Lowney is a senior research assistant at the Addiction Research Foundation.

Dr. Hood is a professor of biology at Caltech and Dr. Hunkapiller is his associate. The Caltech team have developed improved techniques for sequencing peptides and proteins in tiny amounts, thus identifying individual amino acid residues that make up the peptide chain.

The work was made possible by grants from the National Institute on Drug Abuse and the National Institutes of Health, Department of HEW.

The dynorphin story actually began in 1971, with the discovery of specialized receptors for opiates, like morphine, in nerve cells by Goldstein and his colleagues. The existence of these receptors suggested that the body may produce chemicals to fit them.

This theory was borne out four years later, when the Addiction Research Foundation group discovered morphine-like peptides in animal pituitary glands. Other substances, the enkephalins, were found in brain by researchers in Scotland and Sweden.

- more -

These "peptides" are produced in a variety of animals, from earthworms to humans. They are located in various parts of the nervous system, in the pituitary gland at the base of the brain, in the intestine, and in other tissues. Their location in the pituitary, the master gland in the hormone system, suggests that they may regulate hormone secretion or act as hormones themselves.

Immunological methods for detecting the substances were used to "map out" their distribution in the brain. They were found in highest concentrations in those areas associated with pain pathways, and the regulation of emotional activities.

One of these peptides, beta-endorphin, has been tested in humans for its ability to relieve pain, to treat drug addiction, and to reduce symptoms of severe mental illness, but the results are far from conclusive.

At the time of the endorphin discovery, the group at Addiction Research Foundation also found another peptide, which clearly was not related to beta-endorphin. It had a lower molecular weight, was more basic, and had a more persistent effect, as measured by its ability to inhibit electrically-stimulated twitching in isolated guinea pig intestinal muscle.

This muscle is used to test activity of morphine-like compounds because it contains a receptor of the same type that seems to mediate, or unlock, analgesia.

However, the researchers could isolate only small quantities of the substance, too small for the usual tests needed to determine its structure. Conventional sequencing requires milligrams of peptide, much more than had been obtained. So Goldstein turned to the Caltech group.

By increasing the sensitivity of the technique and damping out "background noise," Dr. Hood and his associates have been able to sequence much smaller quantities of peptides and proteins. The procedure employs a step-by-step removal and analysis of the amino acid residues.

The Caltech researchers were able to identify the first 13 residues of dynorphin, using only two micrograms of material. "Theirs is a tremendously improved technique for sequencing tiny amounts of material," Goldstein said. "It is a tour de force".

The first five residues of the identified fragment contained leucine enkephalin, one of the substances discovered in 1975. However, dynorphin is about 700 times more potent than the enkephalin. The researchers believed that the increase in potency was due to the extra residues they had identified.

To test their hypothesis, they synthesized the 13 residue peptide. It proved to be just as potent as the whole natural dynorphin molecule in the biological assay with guinea pig muscle. Less than one billionth of an ounce could completely stop the movements of the small bit of muscle tissue. In addition, naloxone, a drug which selectively blocks the action of morphine-like substances, also blocked dynorhin.

"Now we must answer these questions," Goldstein said. "What does dynorphin do? Where is it found in the brain? Under what conditions is it released? Is an abnormality of dynorphin function implicated in any disease conditions in humans?"

To "map out" the distribution of dynorphin in the brain, Goldstein and his colleagues are developing a radioimmunoassay, using antibodies made against the dynorphin molecule.

This technique also will enable the scientists to test human plasma and cerebrospinal fluid for the substance.

The most exciting aspect of dynorphin, Goldstein said, is that it indicates a level of specificity in these morphine-like peptides not previously recognized.

Ideally, Goldstein said, scientists would like to find a drug that is a strong pain killer, but has no effect on consciousness, and is not addicting.

Dynorpin may lead scientists to a specific receptor, or lock. If dynorphin is found to be a potent analgesic, and if the receptor can be identified, "it could be a big step forward in developing drugs to relieve pain without side effects," he said.

Goldstein also pointed out other areas in which the morphine-like peptides may be involved, such as mood disturbances, blood pressure collapse in shock, temperature regulation, and regulation of the sex hormones. "Dynorphin might turn out to be most selective in one of these functions rather than in pain relief," he said. "Only time and more research will give us the answers."

QUESTIONS AND ANSWERS

gleaned from an interview with Dr. Goldstein by the Stanford University Medical Center News Bureau

Q) *What are the possible roles of dynorphin?*

A) Dynorphin is extremely potent in inhibiting electrically stimulated twitching in isolated guinea pig intestinal muscle, indicating that it binds specifically to receptors involved in analgesia. However, it is not as potent when tested in the mouse vas deferens, which contains a different type of receptor.

When dynorphin was injected into the brains of rats, catalepsy, a loss of voluntary motion observed with morphine, occurred. This indicates that dynorphin also causes changes in behavior.

Q) *How does dynorphin relate to other endorphins?*

A) Dynorphin is structurally unrelated to beta-endorphin but it does have some similar effects.

It contains leucine enkephalin, and may be a precursor molecule to that substance. It is possible that enzymatic breakdown may be Nature's way of "turning off" the action of dynorphin into less active enkephalin. To determine this, we will be trying to see if dynorphin is present in the same nerve cells as the enkephalin.

Q) *Have all the endorphins been discovered?*

A) By no means. There probably is a wide variety of these natural morphine-like compounds, which interact with a variety of opiate receptors. This complex means of interaction is evident in other systems, such as the neurotransmitters, chemical messengers which carry electrical impulses from one nerve cell to another.

Q) *How does this discovery relate to addiction research?*

A) It's too early to tell. One of the theories about addiction to opiate narcotics is that there is interference with the natural morphine-like peptides. The brain may get used to the heroin or morphine, and therefore stop producing endorphins. No such dramatic disturbance has been found, so far, for enkephalins or beta-endorphin. We will certainly want to see what happens to natural dynorphin in animals and humans during narcotic addiction.

- more -

Q) *What impact do you think this discovery will have on understanding pain, and human disease like schizophrenia, in which a role of endorphins has been suggested?*

A) Again, we can only speculate. In pain relief by acupuncture, for example, some endorphin seems to be released, but so far it is not known which one is involved. Possibly it will prove to be dynorphin. Likewise, in schizophrenia, there are suggestive indications that there may be excessive production and release of some endorphin. However, my laboratory recently published an analysis of beta-endorphin in blood of nearly one hundred schizophrenic patients. There were no exceptional elevations in the levels. Again, maybe beta-endorphin is not the peptide that is disturbed in schizophrenia. We will be making similar measurements of dynorphin levels, to see if this new peptide may be implicated.

Q) *Is basic research in neurobiology, of the kind you are doing, really a worthwhile investment for society?*

A) I can't answer that in an objective way, of course, but there are some things worth pointing out. New discovery only comes from basic research. The greatest advances that affect people's health result from new understanding, which leads to new methods of preventing or curing illness--methods that couldn't have been developed before the new information existed. Neuropeptides obviously have a profound influence on human behavior and mental health. Every abnormality of brain function and behavior must reflect some underlying change in brain chemistry. No scientist can predict which discovery of a new brain chemical will open the door to understanding and cure of a particular mental illness, or provide new relief of pain.

Basic research really is the goose that lays the golden eggs. Just as every modern industry invests a significant part of its income in R and D, so must society invest a significant part of its gross national product in basic biomedical research, in order to guarantee—sooner or later—returns in the form of better health for the people. Our own work has been supported generously by the National Institute on Drug Abuse, a government agency. It is important to maintain adequate federal support for all biomedical research and training.

STANFORD—

David I. Sakai has been appointed director of finance at Stanford University Hospital, effective Feb. 3, 1980.

Sakai's appointment was announced by Dr. Peter Levin, associate vice-president and executive director of the hospital.

Levin said the finance director "has wide responsibilities for the managing and planning of the financial operations of the hospital."

Since 1976 Sakai has been chief financial officer of the 500-bed St. Mary's Hospital and Medical Center in San Francisco.

At St. Mary's he has supervised a staff of 95 personnel in accounting, billing, data processing, admitting, clerical and telephone services.

A certified public accountant (CPA), Sakai spearheaded a large reduction in accounts receivable levels at St. Mary's, and supervised reimbursements from Medicare and Medi-Cal.

During 1969-76 Sakai was controller of the medical division of a major hotel-motel chain. The division consisted of six general acute hospitals and six extended care facilities.

He developed standard financial reporting requirements for the division, as well as accounting policies and procedures. Furthermore, he implemented a management information system to supplement monthly financial statements.

Sakai is also a former senior accountant with Arthur Andersen and Co., independent public accountants in San Francisco.

A U.S. Navy veteran, Sakai received his B.S. degree and his M.B.A. from the University of California in Berkeley. He is a member of the American Institute of Certified Public Accountants, the California CPA Society and the Hospital Financial Management Association.

STANFORD—

Noted Stanford cancer researcher, Dr. Henry S. Kaplan, will describe advances in cancer research as part of a two-hour television special, "A Shining Season," to be shown on CBS on Wednesday, December 26.

The program is a dramatization of the life of a young track star, John Baker, who died of cancer in 1970 at the age of 26.

During breaks in the drama, current cancer research will be highlighted and Kaplan will be featured in his laboratory at Stanford Medical School and in interviews filmed in New York City.

The cancer special is sponsored by General Motors on behalf of the General Motors Cancer Research Foundation, established in 1978 to honor prominent individual research achievements in the diagnosis, prevention and causes of cancer.

Last spring, Kaplan, Maureen Lyles D'Ambrogio Professor in radiology, was awarded the Foundation's first Charles F. Kettering Prize for his research on Hodgkin's disease, a cancer of the lymph glands.

"A Shining Season" will be broadcast in the Bay Area on channel 5, KPIX, from 9 to 11 p.m..

Science and medical writers: This story is released jointly with the University of California Medical Center, San Francisco. Embargo time is set by the *New England Journal of Medicine.*

ADVANCE FOR AM PAPERS (PST), THURSDAY, DECEMBER 20, 1979

STANFORD—

Between 27 and 32 percent of hospital deaths related to certain high-risk nonemergency operations could be prevented if these procedures were confined to regional centers, a study by California researchers has disclosed.

The mortality of open-heart surgery, vascular surgery, transurethral resection of the prostate, and coronary bypass is lower in hospitals doing 200 or more of these operations a year, the researchers reported in *The New England Journal of Medicine* Thursday, December 20.

Similarly, the mortality rate of total hip replacement is lower in hospitals doing 50 to 100 or more operations a year.

For simple procedures such as gallbladder removal and vagotomy (surgery to control stomach acid in ulcer patients), the researchers found no relation between the number of operations performed and death rates.

Dr. Harold S. Luft of the University of California in San Francisco, and Drs. John P. Bunker and Alain C. Enthoven of Stanford University said their findings suggest the need for increased regionalization of certain procedures.

The authors said they undertook their study because of the widespread belief that, other things being equal, the quality of medical care improves with the experience of those providing it.

Their purpose was to obtain baseline data as to what surgical loads are required for specific procedures in order to obtain these results.

They said the "experience" hypothesis, if confirmed by others, could have profound implications for the organization of medical care.

"Optimal quality as well as cost savings could potentially be realized through regionalization, they added.

Funded by a grant from the Henry J. Kaiser Family Foundation, the two-year study examined the relationship between surgical load and mortality for 12 operations from 1,500 hospitals and more than 840,000 patients for 1974 and 1975.

The operations ranged in complexity from open heart surgery to gallbladder removal.

- more -

The data for the study were provided by the Commission on Professional Hospital Activities (CPHA) of Ann Arbor, Michigan. In 1974-75, CPHA hospitals represented 29 percent of all U.S. nonfederal, short-term hospitals and accounted for 40 percent of the discharged patients.

Hospitals were categorized by the number of operations performed each year (from one to more than 200) for each surgical procedure, and data were adjusted for patient age, sex and diagnosis.

The study revealed that if all open-heart surgery, vessel surgery, coronary artery bypass grafts, and prostate surgery were performed with the results found in hospitals doing 200 procedures or more annually, the death rate could have been cut 27 percent.

Similarly, if all total hip replacements were performed with the results found in hospitals doing 50 or more procedures a year, the death rate could be reduced 32 percent.

While the study does conclude that a high volume of operations and low mortality go together, it poses another question, the researchers said. Does it explain the cause?

Some hospitals may be well known for having more skillful surgeons and operating room personnel, they noted, and as a result, may attract a larger share of patients suffering from a particular condition.

The study found that for some procedures, such as open-heart surgery and coronary bypass grafts, there was a substantial concentration of patients in hospitals with low death rates.

The researchers conclude that there is a case for regionalization of certain operations, and suggest that the first step should be implementation of a comprehensive regional surgical outcome system to confirm the results of their study and cover operations that were not included in their investigation.

Operations confirmed as having important volume effects should be considered for regionalization, the authors said.

They noted that the guiding principle should be that the greater the risk of low volume surgery, the greater the distance the patient should travel to a health facility with high volumes and good results.

STANFORD—

Dana Redington, a graduate student at University of California at Davis, recently monitored his heart rate and physical activity during the oral examination for his doctorate.

His heart rate, which normally is 72 beats per minute, jumped to 90 beats per minute before the exam, and peaked at 150 when the first question was asked by his examiners.

His heart rate did not return to normal until hours later, when he went to sleep that night.

Redington's experiment was part of a program conducted by researchers at the Stanford Sleep Disorders Clinic and Research Center. Redington is a psychophysiologist at the center. The experiment demonstrates the impact which a stressful situation can have on the body.

Redington was able to record this experience with a small, light-weight package he wore on his belt. Electrode leads from the package recorded his heart rate and physical activity for play back on a computer program later.

The device represents a new technology in solid state electronics, which enables physicians to monitor the vital signs of their patients over long periods of time, and under a variety of conditions outside the hospital.

At the Sleep Disorders Center, for example, the devices are being used to diagnose disorders of the sleep-wake cycle, such as chronic jet lag and shift work problems.

"It is no longer sufficient to look at a single point in time to make a diagnosis," said Dr. Laughton Miles, clinical assistant professor of psychiatry, at a recent seminar in the Sleep Disorders Center.

"Physiological changes related to illness or health must be examined throughout the 24-hour period and in patients' own environments," he said.

In addition to providing a more natural basis for diagnosis, ambulatory monitoring avoids the costs of hospitalization and elaborate clinic testing, Miles said.

Equipment used by the Sleep Disorders Center was developed by Vitalog, Inc., a Palo Alto firm. The research is supported by the Department of Psychiatry and Behavioral Sciences at Stanford University School of Medicine, and by the Institute for Medical Research in San Jose.

- more -

The use of microelectronics in the Sleep Disorders Center developed out of the need to improve diagnosis of often baffling sleep disorders related to a disruption of the normal sleep-wake cycle.

Many patients can't get to sleep at night, then find it difficult to stay awake during the day. This problem may be unrelieved or even made worse by the use of sleeping pills, and can be very disruptive to patients' social and working lives.

Before the advent of microelectronics, abnormal sleep-wake cycles could be diagnosed only by having patients keep sleep diaries, or by monitoring them in the laboratory.

Now acccurate monitoring can be done by machine outside the lab, at much less expense.

With microelectronics has emerged a new field called chronotherapy, the treatment of disturbed sleep-wake cycles.

Developed by researchers at Stanford and at the Sleep-Wake Disorders Unit in New York's Montefiore Hospital, the treatment involves putting patients to bed three hours later every day over a period of five days. This effectively "rewinds" their biological clocks, until the time they go to sleep coincides with their desired bedtime.

The studies are preliminary, cautions Charles Czeisler, Ph.D., a medical student at Stanford who helped design the treatment. However, "for people who have this disorder, chronotherapy can be an important alternative to drugs," he says.

Miles demonstrated the capacity of the ambulatory monitoring devices last summer during a two week train trip across seven time zones in Russia aboard the Trans-Siberian Express. The monitor provided an automatic computer record of shifts in his sleep-wake cycle and body temperature during the trip.

Miles said the devices might have application in determining the alertness of industrial workers and airline pilots, and thus avoiding accidents which occur from human error. They may also help researchers analyze the effectiveness of stress reduction and exercise programs in rehabilitating victims of heart attacks.

STANFORD—

Dr. Edward B. Stinson, a leader in Stanford University's heart transplant program, has been named The Thelma and Henry Doelger Professor of Cardiovascular Surgery.

The Stanford University Board of Trustees established the chair and named Dr. Stinson its first holder Tuesday, December 11.

The chair was endowed by a gift from Mrs. Thelma Doelger of Daly City. Her late husband Henry, a pioneering real estate developer and founder of Doelger Enterprises, built the Westlake district in Daly City and a major portion of San Francisco's Sunset district.

Dr. Stinson, 41 has been a close associate of Dr. Norman E. Shumway, chairman of the Department of Cardiovascular Surgery, since 1969, the year Dr. Shumway performed the first adult human heart transplant in this hemisphere.

"I am enormously pleased," Dr. Shumway said, "to have an endowed professorship in the department to which we could appoint Ed as recognition of his contributions to the department and society."

Dr. Stinson now directs the Stanford heart transplantation program, which is the most successful in the world and the most active in the United States.

Among his contributions was the development, in 1973, of a refined technique for obtaining small samples of heart tissue from patients. These samples, Dr. Stinson explains, are "valuable in diagnosing acute rejection episodes" so that corrective treatment can be provided.

Because of such improvements in the clinical management of Stanford heart transplant patients, nearly 70 percent—all suffering from end-stage heart disease—now survive at least a year. A total of 71 transplant patients are currently alive, two in their ninth year since receiving new hearts at Stanford.

In addition to his work on transplantation, Dr. Stinson heads one of Stanford's two cardiovascular services and is involved in a long-term evaluation of the results of heart valve replacement.

He is also the principal investigator in a national study on unstable angina pectoris (chest pain originating in the heart).

Dr. Stinson and his wife, Donna, are residents of Los Altos. They have two sons: Bret, who attends Los Altos High School, and Colin, a student at Pinewood School.

In addition to Mrs. Doelger's gift of this new professorship, Stanford's heart program is a substantial beneficiary of a charitable trust established by Mr. Doelger's will.

STANFORD—

Monitoring fetal growth, treatment of brain tumors with heat, and cell membrane function are among the research topics of ten young Stanford Medical School scientists selected to receive funds from the Andrew W. Mellon Foundation of New York.

The three-year $400,000 grant to Stanford University School of Medicine will "assist in providing teaching and research opportunities for outstanding young faculty investigators," according to the Foundation.

Stanford is one of 15 private medical schools to receive funds from the Mellon Foundation. The grant is a renewal of the Foundation's 1973 and 1976 programs of similar assistance to these institutions.

Ten young Stanford faculty members in basic and clinical sciences have been selected fellows for 1979-1980 by acting dean and vice-president for medical affairs, Dr. Lawrence G. Crowley.

The recipients are Helen M. Blau, Ph.D. (pharmacology); Richard H. Britt, M.D., Ph.D. (surgery); Dieter R. Enzmann, M.D. (radiology); Richard D. Mamelok, M.D. (medicine); W. Desmond McCallum, M.D. (gynecology and obstetrics); James E. Rothman, Ph.D. (biochemistry); Peter B. Sargent, Ph.D. (structural biology); Carla Jo Shatz, Ph.D. (neurobiology); David K. Stevenson, M.D. (pediatrics); and Bruce G. Wallace, Ph.D. (neurobiology).

* * *

Blau is studying genetic regulation of muscle cell differentiation and development to learn what conrols the transition of an unspecialized cell into a highly specialized muscle cell.

Neural coding in the auditory system is one subject of Britt's research. In addition, he is testing the use of hyperthermia as a new type of treatment for malignant brain tumors. This technique would deliver heat selectively to the tumor without affecting surrounding tissues.

Computerized tomography scanning (a new method of imaging using x-rays and computers) is being tested by Enzmann for distinguishing the stages in brain abscess development, with the goal of making early diagnosis more reliable.

Drug transport systems in kidney cell membranes are being examined by Mamelok, to obtain more information on drug therapy in patients with kidney failure. He also hopes to learn more about avoiding damage to the kidneys when administering potentially toxic drugs.

McCallum is developing a method of accurately estimating fetal volume from ultrasonic images so that fetal growth can be monitored.

Rothman is studying how cell membranes are formed and how different enzymes are directed to specific membranes during cellular growth and division.

Sargent studies the formation of synapses, the areas where nerve cells come into close proximity and influence each other across gaps of just one millionth of an inch.

How cells in the retina of the eye make connections with cells in the brain during development is the subject of Shatz's research. The entire visual system is dependent on information received from the initial nerve connections.

Stevenson is working on techniques for measuring certain types of gases in babies' breath. These measurements can be used by doctors to detect some ailments before they become severe, in time for effective treatment to be started.

Wallace is trying to determine how developing nerve cells accumulate neurotransmitters, the chemical messengers that transport electrical signals accross gaps, or synapses, between the cells.

STANFORD—

Stanford University psychiatrists are studying a natural brain chemical that could provide clues to the development of autism.

They are seeking 200 autistic and severely retarded children to participate in the study.

Autism is an illness that occurs early in infancy and is marked by bizarre flapping and twirling behaviors, emotional withdrawal, and severe language disability. The disorder strikes four to five children per 10,000 yet it continues to baffle scientists.

The brain chemical believed to play a role in autism is serotonin, a substance that carries electrical impulses from one nerve cell to another.

Drs. Roland Ciaranello, assistant professor of psychiatry, and Steve Stahl, resident physician in child psychiatry, are studying a finding that one third of autistic children have abnormally high levels of serotonin in their blood.

Elevated serotonin levels have also been found in 50 percent of severely mentally retarded children whose condition results from unknown causes.

No one understands the significance of elevated serotonin levels, Ciaranello says. "We need to know what causes the elevation, if other family members also have high levels, and, ultimately, what role, if any, it plays in autism."

Participation of children in the study will require the taking of small blood and urine samples, and family histories.

Parents who would like their children to participate in the study should call the Laboratory of Developmental Neurochemistry at (415) 497-6049.

Further details about the study are described below.

Until the mid-1960s, autism was regarded primarily as a psychological illness caused by cold, unloving parents, Ciaranello says.

Now the disorder is viewed as a neurological disease. "It is clear these children have a profound inability to process incoming signals, "he says. In addition, as many as one third of them develop seizures during adolescence.

Today there are sophisticated programs designed to correct the language and educational disability which characterizes autism. Yet, Ciaranello says, this treatment is difficult, and progress is often poor.

"The fate of many autistic children still is institutionalization," he says.

Ciaranello and Stahl hope their study will improve understanding of autism, perhaps as a genetic disorder.

High serotonin levels may provide a means of diagnosing the disorder at birth. Alternatively, the study could lead to discovery of a "critical period" during development, after which brain damage and the resulting clincal signs known as autism occur.

"If we could find out which children are at risk for autism, and reach them before the critical period, perhaps we could prevent the brain damage," Ciaranello says.

However, he cautions that the study is preliminary, and that successful treatment is probably years away.

The study is supported by funds from the Department of Psychiatry and Behavorial Sciences.

STANFORD—

Tuition at Stanford University School of Medicine will increase 12.3% for present students and 20% for new students next fall if the University's Board of Trustees approves an administration recommendation next week.

This means tuition per academic quarter for current students will be $2,289 and for new students will be $2,446.

The tuition proposal was discussed by the administration at a meeting with medical student leaders Monday, December 3.

Medical students now pay $2,038 per academic quarter. That rate currently places Stanford at the median of $6,440 per year for private U.S. medical schools, said David S. P. Hopkins, assistant dean for administration.

Tuition rates at a few private medical schools presently run as high as $13,500 per year, he said.

In accord with a faculty committee recommendation, the administration has proposed that tuition be charged M.D. students for 13 quarters, regardless of the number of quarters registered. For quarters past the thirteenth students will need pay only a special student registration fee which is now $145.

Present students, Hopkins said, will continue to have the option of graduating in 11 or 12 quarters if requirements are met without having to pay the extra quarters of tuition.

John P. Steward, associate dean for student affairs, explained the change is intended to help reverse the trend of increasing number of students who spend four years or less in medical school to save money.

"The new policy will encourage medical students to participate more fully in the Stanford program and elective scholarly activities," he said.

Administration blamed inflation and current economic trends for the proposed increases.

Steward said presently the Medical School's resources appear sufficient to maintain the present commitment of the School to providing financial aid for needy students.

"We will remain committed to meeting the demonstrated need of every M.D. student with loans or a combination of loans and grants-in-aid," he said.

Two-thirds of Stanford medical students are receiving loans and other student aid to help finance their medical education.

Dr. Daniel Nebert, chief of the developmental pharmacology branch of child health and human development at the National Institutes of Health, will present the Pfizer Lectureship on Thursday, Dec. 6, at Stanford University School of Medicine.

The public lecture begins at 4:15 p.m. in Room R-358.

In his studies in rats, Nebert and his researchers have shown that genetic differences in the pathways of drug metabolism may influence the incidence of carcinogenesis (cancer) and teratogenesis (malformation). They have identified an organism in this species which seems to be associated with predictable development of neoplasms.

In his lecture, Nebert will discuss how the activity of drug metabolizing enzymes, which lead to cancerous compounds, is regulated by a genetically inherited receptor in cells.

The Pfizer Lectures are sponsored by the Division of Clinical Pharmacology and the Department of Pharmacology at Stanford Medical School. They are funded by Pfizer Pharmaceuticals, Pfizer Inc. of New York City.

STANFORD—

Stanford University medical students plan to pursue full time academic careers in basic or clinical sciences at more than twice the rate for medical students nationwide, according to a survey conducted by the American Association of Medical Colleges (AAMC).

Forty seven percent of the survey respondents from Stanford Medical School's graduating class of 1979 would like to become faculty members at an academic institution as opposed to twenty percent of such medical students who responded to the questionnaire nationwide.

The survey also revealed that Stanford medical students:

- engaged in research during their medical school years at twice the national rate, and
- used freedom within the academic curriculum for educational purposes (overseas study, clerkships, research) at twice the national rate.

Forty two percent of Stanford medical students who responded had participated in a research project compared with 24 percent nationally, and 30 percent were authors of a research paper as opposed to 15 percent nationally.

Amid growing national concern over future opportunities for medical researchers, assessing changes in student attitudes was one purpose of the survey, according to Dr. Elizabeth Short, assistant dean for student affairs in Stanford's School of Medicine.

One unexpected result was that uncertain availability of research funds is not significantly deterring Stanford medical students from pursuing research careers, Short said.

"Stanford students seem to aspire to research careers for idealistic reasons," she said. "The challenge of the search for new knowledge was a strong motivation for incorporating research into career plans.

"However, uncertain availability of research training and research funds, and the financial disadvantages of a research career were negligible influences on the students' career choices," she added.

Although none of the medical students responding from Stanford (or nationwide) anticipated a career exclusively devoted to research, 67 percent of the Stanford group expected to be involved in research in the future.

Twenty two percent of these students expected to devote as much as several years full time or at least 25 percent of a continuous career to research, in contrast to nine percent of students nationwide.

Other factors strongly influencing Stanford students' penchant for research revealed by the questionnaire were their research experiences during medical school and the opportunity of working in an academic community.

In the two years the AAMC has conducted the survey, Stanford's flexible curriculum, pass/fail grading system, preclinical program, and faculty, were consistently reported as major strengths by the graduating students.

Clinical teaching and the small patient population were considered weaknesses by responding students.

And while the postgraduate financial outlook does not concern them, problems with high tuition and financial aid during medical school are increasingly worrying Stanford medical students, according to the survey.

STANFORD—

A new suite for the study of hyperthermia in treating cancer was dedicated Monday, January 28, in the division of radiation therapy at Stanford University School of Medicine.

Hyperthermia refers to the heating of tissue. Stanford researchers under the direction of Drs. George M. Hahn and Jane B. Marmor have found that heating by ultrasound effectively shrinks some solid tumors in patients, particularly surface tumors in the head and neck region.

Construction of the hyperthermia suite was made possible by a gift from Virginia and Dean Morrison of Piedmont, California. Mr. Morrison, a 1930 graduate of Stanford University, is chairman of Morrison Homes of Pleasant Hill. The Morrisons also support an endowed chair in their name at Stanford in population studies.

"We are very grateful to the Morrisons for their gift," said Dr. Malcolm Bagshaw, chairman of the Department of Radiology and director of the suite. "The new suite will make it possible for the Department to treat more patients and expand clinical research on this promising new technique."

Current projects include development of ultrasound transducer arrays, which will allow treatment of larger and some deeper tumors, and combination of hyperthermia with both radiation and chemotherapy.

Scientists have known since the 1890s that heat can shrink tumors. However, systematic study of the technique was not possible until the 1970s, when developments in ultrasound and microwave technology improved the dependability of heat sources.

Parallel developments in microelectronics enabled physicians to monitor directly the temperature changes which occurred in tissue upon heating.

In 1970, Hahn began studying the effects of heat on cells, using ultrasound equipment developed with the help of Douglas Pounds, a thermal physicist.

Later, the studies were applied to animals, and in 1976, Hahn and Marmor found that ultrasound heating caused shrinkage in 50 percent of surface tumors in dogs, cats and mice.

Last year they reported shrinkage in nearly 70 percent of superficial head and neck tumors, and in 50 percent of a variety of surface tumors in 30 patients treated with hyperthermia.

FOR IMMEDIATE RELEASE

STANFORD—

During the past six years, Stanford failed to meet its own affirmative action goals for hiring Medical School faculty, a federal report charges.

Other schools within the University met faculty hiring goals, but failed to meet their targets for retention and promotion of female and minority faculty, according to an amended 30-day "show cause" notice from the San Jose regional Office of Federal Contract Compliance Programs.

Based on a three-month review by two compliance officers on campus, the University was cited for 15 deficiencies. Stanford Affirmative Action Officer Santiago Rodriguez called the list "significant and substantive, although not unexpected."

The University has cooperated closely with the compliance review. Rodriguez expressed confidence that satisfactory remedies can be developed for the deficiencies cited.

The transfer of affirmative action compliance provisions from the Department of Health Education and Welfare to OFCCP has resulted in a general tightening of standards, including more dramatic charges and antagonistic responses from other major universities.

At the November meeting of the Faculty Senate, Provost Donald Kennedy disclosed he was forming three task forces to identify women faculty of "unarguable quality" and bring them to the attention of deans and departments with vacancies.

Kennedy told the Senate that chicano faculty are "very significantly below any reasonable definition of critical mass" and said the University had suffered "attrition from the early 1970s" in black faculty. "We need to do more, especially in attracting and retaining junior faculty," he said.

Corrective actions demanded by OFCCP include:

* Developing staff affirmative action goals and timetables within each vice-presidential area, with objectives for hiring and promotions to be met in no more than five years.

* Revising internal reporting systems to measure the effectiveness of the total affirmative action program, including data on all applicants, new hires, promotions, terminations, transfers, layoffs, and recalls.

* Including performance on equal employment opportunity in the performance reviews of supervisors, managers, department chairpersons, and deans; and

* Revising job groups for faculty and other academic staff "to include faculty positions from departments having similar academic disciplines and common administrative control (under a single dean)." Within these related areas, separate job groups should be developed for 1) tenured faculty; 2) nontenured faculty, 3) lecturers, and 4) research associates.

University officials have been asked to meet later this month with OFCCP officials to develop a written conciliation agreement, indicating how the deficiencies can be met. Stanford may seek an extension in the 30-day limit which ends in mid-February.

From 1974-75 through 1979-80, Stanford "failed to meet its hiring goals for minorities and female faculty members without sufficient justification" in two areas, the report declared.

- more -

In medicine basic sciences, the University's affirmative action plan projected 45 appointments, including one black, during this six-year period. There were actually 21 appointments, none of which was black.

In 1974 there were no blacks in the job group among 60 faculty. There still are no blacks among 46 faculty this year.

In medicine clinical sciences, the 1974 plan projected 137 faculty appointments, including two blacks and five Asians, over six years. Of the 172 faculty actually appointed, three were Asian and none black. Out of the 224 faculty in this job group in 1974 two (.9%) were black. Now there are none. Asians increased from five (2.2%) to seven (2.3%) over the same six-year period.

"Although Stanford's hiring goals were attained in every other goal area, minorities and females did not experience any increase in their utilization and in some cases experienced a decrease in representation, despite the existence of an affirmative action program and substantial opportunities to effect affirmative action," the report observed.

In other words, hiring gains were offset by subsequent losses over the six year period. In the total selection process for Stanford faculty:

* There were approximately 94 direct appointments to tenure during the six-year goal period, of which only four (or 4.2%) were women, two (or 2.1%) were black, one (or 1.1%) hispanic, and four (or 4.2%) were Asian.

* There were 163 faculty members promited to tenure, of which only 16 (or 9.8%) were women, four (or 2.5%) were black, four (or 2.5%) were hispanic, and five (or 3.1%) were Asian.

Where previous goals were not met, Stanford must establish "make up goals" to remedy its past failures in addition to future requirements, the federal report indicated.

On the staff side, the OFCCP points out the need for developing more accurate job groups. "Management and supervisory job(s). . .should be grouped by their level of responsibility—for example, first, mid- and top-level management." The present groups combine professional lawyers with legal assistants, administrative assistant IIIs have been classified as "executives, administrative and managerial, yet clearly do not meet the criteria. . .for this category," the report noted.

Rodriguez indicated that OFCCP has offered technical assistance in helping the University make these changes. He said the likely result is an increase in the total number of job groups used in affirmative action reporting. These now total about 40.

FOR IMMEDIATE RELEASE

STANFORD—

Does your blood pressure rise during periods of stress at home or on the job, or do you experience unpleasant side effects while taking medication for high blood pressure?

If your answer to either of these questions is "yes" you are invited to participate in blood pressure management training being offered by Stanford University Medical School.

The blood pressure training, which is free of charge, is designed for a "significant group" of patients who do not respond well to standard medical treatment, according to Dr. Craig K. Ewart.

The training is part of a research project being directed by Ewart and Dr. C. Barr Taylor.

In recent years researchers at Stanford and elsewhere have begun to use techniques such as relaxation, meditation and reflective stress analysis to lower blood pressure. Ewart and Taylor and trying to determine if these methods can help those who do not respond to drug therapies.

A novel feature of the project, Ewart noted, is inclusion of of the patient's spouse or intimate friend in the training.

If the training is to be effective, he explained, the patient must use stress control methods regularly in his or her normal environment.

"It is a lot easier to apply these skills in everyday situations if you have a partner who can help," he commented. "an understanding wife or husband can do a lot to help you reduce the amount of stress in your life."

The eight weeks of training is provided on an individual couple basis, and consists of weekly, hour-long sessions, tailored to the individual needs of each couple.

Sessions will be held in the Stress Relief Clinic.

Persons wishing to participate in the program, or those who need additional information may call the Stanford Health Behavior Program at 327-2873 weekdays between 8 a.m. and 5 p.m.

(ADVANCE) FOR AM PAPERS THURSDAY, JANUARY 24, 1980

Science Desks: A press conference to present the report of the Joint Commission on Prescription Use will be held at 2 p.m. Wednesday, January 23, in 4232 Dirksen Office Bldg., Washington, D.C. Commission contact numbers are Kenneth Melmon, M.D., chairman, (415) 497-5454 or Marcus M. Reidenberg, M.D., vice chairman, (212) 472-6030.

WASHINGTON, D.C.—

A comprehensive monitoring system for evaluating the actual risks and benefits of marketed prescription drugs was recommended Thursday, January 24 by the Joint Commission on Prescription Use.

In a 153-page report reflecting three years of research, the commission called both for intensified efforts on the part of the U.S. Food and Drug Administration (FDA), and for the creation of a private,, nonprofit national Center for Drug Surveillance to engage in activities not covered by existing programs.

"A better coordinated and more comprehensive system of postmarketing drug surveillance should be established in the United States," the commission said.

Monitoring, the commission added, is needed because desirable or necessary information about prescription drugs is unavailable from premarketing studies. The limited number of patients participating in such studies restricts what can be revealed about drug effects.

The commission was formed three years ago at the request of Senator Edward M. Kennedy, chairman of the Senate Subcommittee on Health. The commission was asked to determine if there was a need for such monitoring system and, if so, how it should be structured most efficiently.

Noting that a stepped up surveillance program for marketed drugs should be a high FDA priority, the commission said a Center for Drug Surveillance was needed to complement and augment the responsibilities of the FDA and other research endeavors both public and private.

With initial recommended funding of $10 million a year, the commission said the center would work to educate all members of society who use and distribute pharmaceutical products, develop new programs and methods for postmarketing surveillance, train scientists and foster cooperation.

The report was made public by Dr. Kenneth L. Melmon, professor and chairman of the department of medicine at Stanford University, who chaired the 18-member commission.

Senator Kennedy, Dr. Theodore Cooper, then HEW assistant secretary for health, and Dr. David Hamburg, president of the Institute of Medicine-National Academy of Sciences, selected the commission's membership representing medicine, pharmacy, the pharmaceutical industry, hospital administration, and consumer and public interests.

For the past three years, the commission reviewed the need for surveillance of marketed drugs, and the development of a system that could be used to detect, quantitate and describe the anticipated and unanticipated effects of drugs used in medical practice.

The commission noted there are presently about 54,000 drug products on the market, representing 1,900 active ingredients, with 1,024 new chemicals introduced since 1940.

-more-

These drugs are studied both in the laboratory and in animals for pharmacological and toxic effects prior to approval for studies in humans. The drugs undergo a three-phase testing before being released for marketing.

The studies, usually conducted in 500 to 3,000 volunteers, are designed to determine a drug's dose range and tolerance in humans, efficacy for one or more clinical conditions, and adverse effects. Controlled and uncontrolled clinical studies are used to demonstrate efficacy and to provide the primary information on safety.

If these trials confirm the drug's efficacy for the intended conditions with acceptable toxicity, the drug is approved.

Once marketed, despite restrictions implied in the official label, a drug can be used in any dosage for any indication considered medically appropriate. FDA regulation continues only to assure that the procedures and safeguards for manufacturing established during approval are maintained.

The commission said surveillance of marketed drugs includes many separate programs at the present time. They include voluntary reporting to FDA, to drug companies, and to the professions through medical and scientific journals, research programs based in universities, ad hoc studies, and research sometimes required of pharmaceutical companies by the FDA as a condition for marketing.

"These programs are functioning well, but they should be integrated," the commission said.

Hints of drug effects that will bear on medical and regulatory decisions may be detectable long before effects are clearly recognized and even longer before the information is used clinically, the commission pointed out.

It is the role of surveillance to detect systematically these hints, test whether they are pointing to real effects, and facilitate the use of this clinical information.

Thus, the beneficial or harmful (expected and unexpected) effects of prescription drugs as they are used in medical practice can be monitored and determined, the commission added.

With current methods, the commission noted, the system could be used to study expected or unexpected toxicity and unintended efficacy, successfully detecting events that occur with a frequency of at least one event per 1,000 exposures.

The commission said multiple types of reports will be necessary, tailored to the differing needs of recipients, to disseminate the drug information.

"The information gained is useful only when it is reported to those who can use it," the commission said.

The problem of monitoring marketed drugs is a worldwide concern, the commission said. Considerable strides have been made both in the U.S. and elsewhere to make such monitoring more systematic. The United Kingdom and other countries have either proposed or begun to implement innovative new methods for drug monitoring.

STANFORD—

James H. Dewson III has been appointed director of the Division of Laboratory Animal Medicine at Stanford University School of Medicine.

His appointment was announced jointly by Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the medical school, and by Gerald J. Lieberman, vice provost and dean of research at Stanford.

Dewson has served as acting director since last March. He succeeds Dr. Orland A. Soave, who retired earlier this year.

The Division of Laboratory Animal Medicine supports medical and scientific research at Stanford. The division operates about 30,000 square feet of animal space in nine different locations on campus.

An administrative panel appointed by the university president serves in an advisory and general policy-making capacity for the division. The panel helps insure that the university meets its ethical and legal responsibilities in the care and humane treatment of its animals.

Dewson is associate professor of hearing and speech sciences in the Department of Surgery, and previously was chairman of the administrative panel.

Dewson's research with monkeys led to the discovery in 1976 that these primates possess a type of brain which had earlier been associated with man's specific intellectual capacities.

A graduate of the University of Arizona, Dewson received his Ph.D. from Stanford Medical School in 1961. Except for three years (1967-69) when he taught and conducted research at Oxford, Dewson's professional career has been at Stanford when he began as a postdoctoral fellow in the Department of Psychiatry in 1961.

STANFORD—

Patient occupancy at Stanford University Hospital is the highest it has been in three years, according to Hospital administrator Gary Mecklenburg.

For the past four months, September through December, there have been 20 to 30 more patients in the Hospital every day than the level anticipated in the budget (about 450 patients per day).

Mecklenburg said the higher occupancy has caused difficulties for the admitting, nursing and Emergency Department staffs.

In the last two weeks for example, several emergency patients had to wait in the Emergency Department overnight for a bed to become available.

Some of the high risk newborns and pregnant women normally transported to Stanford's intensive care nursery and delivery rooms have been taken to other hospitals in the region. And shortages of beds in the intensive care units (ICUs) have meant that some elective surgeries have been postponed.

The high census is not limited to Stanford, Mecklenburg said, but seems to be a regional phenomenon. Maternity cases at El Camino Hospital in Mountain View increased 11 percent in the period July, 1979 to January, 1980, compared with the same period last year, and overall occupancy this month has been high, according to assistant administrator Harvey Hansen. This resulted in the closing of the El Camino's emergency room for two days in the last two weeks, and the transfer of several patients to Stanford.

Sequoia Hospital in Redwood City has had an occupancy rate of up to 300 patients per day since New Year's, 50 more patients per day than normal. In addition, San Jose Hospital, Santa Clara Valley Medical Center in San Jose, and the Palo Alto Veterans Administration Medical Center have been more full than usual.

The increased patient occupancy throughout the area has increased competition for the nurses needed to staff extra beds at Stanford, Mecklenburg said.

In September, 1979, there were 56 vacancies for nursing positions at Stanford, 11 of those in the operating rooms. The gap has closed somewhat as the result of vigorous recruiting by the Personnel Department and Nursing Service, but there still were 43 vacancies as of January 1, six of them in the operating room.

Some beds remain unused because of a lack of nurses needed to staff them.

To adjust to the continued high occupancy, the Hospital has instituted a variety of measures.

On January 14, a 14-bed unit at the Hoover Pavilion was reopened, and an additional 10 beds at Hoover will become available later this week.

- more -

The medical staff has approved new policies which call for admitting the sickest patients first, and allowing postponement of elective procedures.

Administrators are considering opening the temporary use of ICU beds as a pre-operative unit. Such a unit would not require as many nurses as an ICU does, and would get more patients into the Hospital more quickly, Mecklenburg said.

In the short run, the Palo Alto VA Medical Center may accept several specialty patients from Stanford, under an existing agreement.

And the Personnel Department and Nursing Service are undertaking several measures designed to increase the number of nursing recruits. These include providing rental apartments on a short term basis for nurses who come from outside the Bay area, changing the salary program to account for job experience, and improving the compensation package for relief nurses.

Apartments were made available in January, and the other changes will take place next month, according to Don Thomas, personnel director. Thomas encouraged all Hospital and medical staff to participate in the recruitment efforts.

Although several hospitals in the area periodically close their emergency rooms during periods of high occupancy, Mecklenburg said that Stanford will keep its Emergency Department open in any way possible.

"We are in a geographical location in which we have no other hospitals nearby for backup," he said, "and we would rather that patients receive care here than spend valuable treatment time riding in an ambulance to another hospital."

Mecklenburg said several factors may have contributed to the high occupancy at Stanford.

First, an increase in the numbers of hospitalized patients traditionally occurs in the period immediately following the holidays.

Secondly, greater numbers of referrals to Stanford occur when other hospitals have heavy patient populations. Stanford also offers new services which are attracting more patients. For example, 68 patients were transported to Stanford last year under the newly-established adult emergency medical transport service.

Finally, population growth in Santa Clara County may be contributing to high patient occupancy in area hospitals, Mecklenburg said.

Mecklenburg said the high occupancy probably would last through March.

"The cooperation of all Hospital employees, nurses and medical staff has been tremendous," he said, "particularly under such difficult circumstances."

STANFORD—

Is the lower rate of heart disease among runners due to a "genetic protection" against the disease, rather than to the exercise itself?

A Stanford University professor refuted this suggestion, in a letter published in the current issue of the *New England Journal of Medicine.*

In the letter, Dr. Ralph S. Paffenbarger, Jr., professor of epidemiology at Stanford University School of Medicine, cited a study of 16,936 Harvard University male alumni to show that parental histories of heart disease did not differ significantly between those who participated in vigorous sports and those who were less active.

A previous study had suggested that the incidence of heart disease among parents of long distance runners is less than that of non-runners, making the runners a self-selected group which is genetically protected against the disease.

On the contrary, Paffenbarger wrote, the Harvard study "tends to refute suggestions that selection establishes exercise habits, determined by inherited or other familial characteristics, which in turn influences heart attack risk."

He stated it was likely that "sons of physically active parents would carry on their family life-style by being physically active themselves," but this does not refute the hypothesis that exercise contributed to their lower heart attack risk.

In fact, "exercise would tend to reduce the influence of adverse hereditary and familial circumstances," he added.

Paffenbarger analyzed five different risk factors for heart attack in the men, who graduated from Harvard between 1916 and 1954: cigarette smoking, obesity, high blood pressure, physical inactivity, and familial tendencies (both genetic and environmental).

The relative risk of heart attacks among those who expended less than 2000 kilocalories per week in exercise was 49 percent higher than their more active counterparts.

Thirty three percent of that risk may be attributable to a sedentary life-style alone, he wrote.

Hypertensive alumni had 134 percent greater risk of heart attack than those with normal blood pressure. Cigarette smokers had a 30 percent greater risk than non-smokers, obese men had a 32 percent greater risk than their leaner counterparts, and men who reported a family history of heart disease had a 28 percent greater risk than those who denied such a history.

"Thus, each of these five characteristics makes an independent and significant contribution to heart attack risk," Paffenbarger wrote .

In an interview, Paffenbarger said that the debate over the benefits of exercise will continue until its relation to heart disease is determined, and until the disease itself is better understood.

But although it is not established conclusively that exercise can lengthen life, "there is no doubt that it improves the quality of life," he said. "That is surely one of the chief dividends of good health."

STANFORD—

Two Stanford University professors have been named recipients of the prestigious National Medal of Science, to be presented by President Carter early this year at a White House ceremony.

Dr. Donald E. Knuth, Fletcher Jones Professor of computer sciences, and Dr. Arthur Kornberg, Emma Pfeiffer Merner Professor of biochemistry, are among 20 recipients of the award, the nation's highest honor for distinguished achievement in science, mathematics and engineering.

Knuth and Kornberg bring to 12 the number of medal recipients from Stanford since the award was established by Congress in 1959 to honor persons "deserving of special recognition by reason of their outstanding contribution to knowledge in the physical, biological, mathematical or engineering sciences."

Previous Stanford winners are Profs. Paul J. Cohen, George B. Dantzig, Carl Djerassi, Paul Flory, the late Rudolf Kompfner, Wolfgang Panofsky, Linus Pauling, Henry Taube, Frederick E. Terman, and Cornelius van Niel.

Knuth is widely recognized for his research in the analysis of algorithms, the basic procedures by which computations are performed. He is also a recognized authority in the early history of programming languages and computing machines.

In addition, Knuth is the author of a series of books widely acclaimed in the field, *The Art of Computer Programming.* The series is an attempt to compile and organize the entire body of scientific material on programming of digital computers, and has contributed significantly to the establishment of computer science as a scholarly discipline.

Born in 1938 in Milwaukee, Knuth received a B.S. degree from Case Institute of Technology in 1960, and a Ph.D. from California Institute of Technology in 1963. In 1968, he joined the Stanford faculty.

A member of the National Academy of Sciences and the American Academy of Arts and Sciences, Knuth is also the recipient of several awards, including the 1971 Grace Murray Hopper Award and the 1974 Alan Turing Award, both from the Association for Computing Machinery, and the 1975 Lester R. Ford Award from the Mathematical Association of America.

A noted biochemist, Kornberg has made major contributions towards understanding replication of DNA, the primary genetic material of living things. His current research focuses on the nature of the replication process, including the mechanisms by which the long DNA chains begin replication, and the complex nature of the proteins required for initiation of DNA synthesis.

- more -

Kornberg pioneered the synthesis of DNA in the laboratory, a feat for which he shared a Nobel Prize in 1959, and he has also worked out the synthetic pathways of nucleotides, the chemical precursor units of DNA.

Throughout the years, Kornberg has been a strong advocate of basic research in science, through public testimony, in speeches and in articles.

A native of New York, born in 1918, Kornberg received a B.S. degree from the City College of New York in 1937, and an M.D. degree from the University of Rochester in 1941.

In 1959, he joined the Stanford faculty as chairman of the department of biochemistry, a position he held for 10 years.

In addition to the Nobel Prize, Kornberg has received numerous awards and honors, including the 1968 Borden Award from the American Association of Medical Colleges, the 1968 Scientific Achievement Award of the American Medical Association, and nearly a dozen honorary degrees.

His publications number in the hundreds, and he is a member of the National Academy of Sciences, a foreign member of Britain's Royal Society, a member of the American Philosophical Society, and is a past president of the American Society of Biological Chemists.

STANFORD—

A new book about DNA, the basic matter of life that determines how cells should function and reproduce, has been authored by Dr. Arthur Kornberg, a Stanford University Nobel Laureate and one of the leaders in the field.

Titled *DNA Replication* (W.H. Freeman and Company, San Francisco, 724 pages, $32.50), the book contains over 300 color illustrations and is written at such a level that it will be useful to DNA researchers as well as to persons interested in supplementing their biochemical knowledge of the subject.

The new book builds on Kornberg's earlier work, *DNA Synthesis* published in 1974. That book covered the biochemical rather than the physiological aspects of DNA synthesis.

"I did not anticipate how little I would retain (of the early book), and how much would have to be added," Kornberg writes in the introduction.

He adds recent advances have produced a qualitative change and justified a larger scope.

The new book, according to Kornberg, embraces biochemical, genetic and physiological aspects, and also the numerous DNA transactions that determine the structure and function of the genetic material.

The first part deals with the explosive advances in genetic chemistry in terms of the structure of the genetic substance DNA. It is followed by presentations of the greatly expanded field of DNA enzymology, one aspect of which is the DNA repair system when mutations are introduced by agents ranging from chemicals to x rays.

This work, derived from bacterial studies, has preoccupied part of the Kornberg laboratory for the past 14 years. Biochemical and genetic studies with these mutants have provided new insights into how DNA is constantly evolving.

For an understanding of replication mechanisms, Kornberg gives an account of present knowledge. This is based on the use of small, well-characterized DNA viruses as tools to study DNA replication events. The structure of these viruses, their mechanisms of infection and replication, and genetic studies are presented.

The synthesis of genes and chromosomes and the newest developments in recombinant DNA research are discussed at the end of the book.

In recent years, writes Kornberg, refinements in analytic methods have uncovered unanticipated subtleties in the organization, replication, and expression of DNA.

The revised concepts have "made the present era one of continuing dreams and promise," he adds.

STANFORD—

A special flashlight to help individuals with severe night blindness has been designed by a Stanford University professor.

The new light is the least expensive and most readily available device to help thousands of individuals who have difficulty moving in the dark because of night blindness and tunnel vision caused by certain eye diseases, according to Dr. Michael Marmor, assistant professor of surgery (ophthalmology) at Stanford.

Marmor is also chief of the ophthalmology section at the Palo Alto Veterans Administration Medical Center (VAMC).

The flashlight, named the Wide Angle Mobility Light (WAML), has a high intensity bulb and broad beam (measuring 20 degrees vertically and 30 degrees horizontally) which combine to overcome the problems facing many patients with retinitis pigmentosa, Marmor said.

"Retinitis pigmentosa involves progressive loss of visual cells in the eye, particularly in the periphery of the retina, causing tunnel vision.

"Since the peripheral areas of the retina are also most sensitive to light, night vision is impaired," he added.

A conventional flashlight does not help because it casts a narrow beam that individuals with tunnel vision cannot easily locate in their field of view.

But the broad intense beam of the new flashlight "is easy for people with tunnel vision to follow," he explained.

The Wide Angle Mobility Light is manufactured and sold by a scuba diving equipment firm, Farallon Industries (Department E) of Belmont, California, and is a modified version of a diving light.

For $84, the five-pound light comes equipped with a special wide beam, high intensity bulb, rechargeable battery (each charge provides one continuous hour of light) and shoulder and waist straps which allow the light to be carried with the hands free.

"This permits the individual not only to move around, but to do chores if desired," explained Marmor.

"The waist strap is also useful because a light should be carried low to the ground so that irregularities in the surface will be shown in sharpest relief," he added.

Marmor noted that patients with night blindness and restricted peripheral vision who have tried out the light have been able to walk almost as freely at night as during the day.

"Although it's still more expensive than I would like, it should be affordable to the average patient and is considerably less expensive than other devices available," he said.

The Wide Angle Mobility Light was introduced last October, and Marmor hopes to get the word out to individulas who could be helped, notably those with retinitis pigmentosa or severe glaucoma.

He also encourages those who buy the light to return the enclosed questionnaire so that the design can be further improved, based on users' suggestions.

Marmor designed the WAML in collaboration with Mr. Ralph Shamlian, an expert on small lamps and batteries, and president of Tekna, a Menlo Park firm. Mr. Carroll Ault, a social worker in the Western Regional Blind Rehabilitation Center at the VAMC, helped in evaluation of early models of the light.

Memorial services will be held on Wednesday, February 27 at Stanford University for Dr. Abraham White, consulting professor in the department of biochemistry, who died on February 14 in Santa Barbara at the age of 72.

Services will begin at 4:30 p.m. in Fairchild Auditorium in the Medical Center.

Principal scientist in the Institute of Biological Science of Syntex Research and former chairman of the department of biochemistry and associate dean of the Albert Einstein College of Medicine of Yeshiva University, Dr. White had also played an active role in the department of biochemistry's teaching programs at Stanford Medical School since 1972.

He died in Santa Barbara just before he was to deliver a lecture at the University of California campus.

An internationally known biochemist, Dr. White also was instrumental in establishing the Albert Einstein College of Medicine at Yeshiva University.

Prior to joining the faculty at Yeshiva, Dr. White had been vice president and director of research in the United States for Syntex during the early years of the company, from 1951 until 1953.

He rejoined Syntex in 1972.

Considered a world authority on the biochemical study of hormones, Dr. White most recently had been a leader in research on hormones of the thymus gland.

He was also coauthor of a widely used biochemistry textbook, *Principles of Biochemistry*, now in its sixth edition.

During his scientific career, Dr. White received numerous honors including the Eli Lilly award in biological chemistry for isolating a pituitary hormone in crystalline form, the distinguished alumni award from the Universities of Denver and Michigan, an honorary degree from Yeshiva University and election to membership in the National Academy of Sciences.

In addition to attending memorial services, friends and colleagues who wish to pay respects to the memory of Dr. White, may do so through contributions in Dr. White's name to the Albert Einstein College of Medicine of Yeshiva University, 1300 Morris Park Avenue, Bronx, New York 10461.

The third and final winter Progress in Medicine Lecture on Plastic and Reconstructive Surgery will be held Tuesday, February 26 in Fairchild Auditorium, beginning at 7:30 p.m..

Drs. Donald R. Laub and Lars M. Vistnes will discuss "Aesthetic surgery to redesign the face, breast and other features."

The lecture is free and open to the public.

Laub, of the Palo Alto Medical Clinic, was formerly associate professor of surgery at Stanford and was chief of Stanford's division of plastic and reconstructive surgery from 1967 until he resigned this year.

He is the founder and president of Interplast, Inc., an organization of physicians who provide free medical care to people in Latin America and in the South Pacific.

Laub also directed the Gender Dysphoria Program at Stanford, providing psychological counseling, and hormonal and surgical treatment of transsexuality.

He will talk about body image and the reconstructive surgical procedures applied to redesign various body features.

Vistnes, associate professor of surgery at Stanford and chief of surgery at the Palo Alto Veterans Administration Medical Center, will talk about aesthetic surgery of the face, including ears, nose, eyelids, and face and neck lifts.

A specialist in wound healing, he currently is studying how tissue responds to silicone, a material widely used in plastic surgery. He also is investigating tissue responses to pressure, particularly in relation to the formation and prevention of pressure sores in paraplegic patients.

Vistnes has also done pioneering work on reconstructive techniques for eye sockets of individuals who have lost an eye. Known as orbital reconstruction, this surgery enables such people to wear a prosthetic eye.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of Stanford's School of Medicine and by members of the Medical Center Council.

STANFORD—

The seventh annual Katharine D. McCormick Distinguished Lecture at Stanford University School of Medicine will be presented by Dr. Rose O. Payne, professor of medicine, on Monday, March 3.

Her public lecture, which is entitled "Footprints on the Lymphocyte Surface—HLA," will begin at 5 p.m. in Fairchild Auditorium at the Medical School.

Her address will be the first to be delivered by a Stanford scientist since the lecture series began in 1974.

Payne is regarded as a pioneer in the study of the HLA system. In fact, her investigation of febrile transfusion reactions led directly to discovery of the HLA system.

She has had a central role in tissue typing for histocompatability studies and has made major contributions to understanding of the relationship of these cell surface markers to disease states.

She received her B.S., M.S. and Ph.D from the University of Washington, and joined Stanford Medical School in 1951. In 1964 she was presented the John Elliott Memorial Award of the American Association of Blood Banks for her research in leukocyte immunology.

Payne was one of the founders of the Professional Women of Stanford Medical School, a group that was organized as a direct result of the McCormick bequest.

The McCormick Lectureship honors Katharine Dexter McCormick, whose gift to Stanford Medical School was with the expressed hope was that it be used "for the encouragement and asssistance of women in pursuing the study of medicine, in teaching medicine and in engaging in medical research."

The annual lecture attracts outstanding women physicians and scientists to lecture at Stanford. Among the well known women scientists who have presented McCormick Lectures are Drs. Rosalyn Yalow and Rita Levi-Montalcini.

STANFORD—

A major unit for the study and treatment of abnormal heart rhythms (arrhythmias) was established recently at Stanford University School of Medicine.

One of only a handful in the United States, the unit employs sophisticated new techniques for characterizing and treating this major health problem.

An arrhythmia is an interference with the normal electrical conduction of the heart. If untreated, it can lead to heart failure and sudden death.

Currently, 20 new inpatients are treated in the unit each month, and between one third and one half of all patients on the Stanford cardiology service at any one time have arrhythmias, according to Dr. Jay Mason, the cardiologist who directs the unit.

"We hope to become the major referral center in the Western United States for this kind of heart condition," says Dr. Edward Stinson, Doelger Professor of Cardiovascular Surgery and a member of the unit.

Other members include Dr. Roger Winkle, co-director, and Dr. Jerry Griffin, a pacemaker specialist in the cardiology division. Others associated with the unit include Robert E. Kates, Ph.D., director of the Stanford Drug Assay Laboratory, Dr. Donald C. Harrison, head of the cardiology division, and Dr. E.W. Hancock, professor of cardiology.

Arrhythmias most often are caused by heart disease, and occur frequently in patients who have suffered previous heart attacks.

The border between dead heart muscle which was killed during the attack and healthy tissue seems to "short circuit" the normal conduction of electrical signals through the heart, Mason says, causing rapid beating of the lower heart chambers, the ventricles.

Unless this rapid beating is in some way corrected, it may compromise the ability of the heart to pump blood and lead to heart failure or death.

Until recently, arrhythmias were treated primarily by implanting pacemakers in the heart, or by administering one of a battery of antiarrhythmic drugs.

Unfortunately, physicians had to rely on trial and error to determine which drugs were effective. If a given drug did not work another would be tried, but in the meantime the patients were exposed to potentially life-threatening arrhythmias.

- more -

Now, Mason and his colleagues have devised a way of determining with greater certainty whether a drug is effective or not, before the patient leaves the hospital.

The technique involves placing a catheter, or thin tube, into the heart of the patient in the catheterization laboratory. Fast beating of the heart is begun, then stopped, by an electrode at the tip of the catheter.

Next, an antiarrhythmic drug is given to the patient intravenously, and the physicians try to re-initiate the abnormal rhythm. "If we can't," Mason says, "we know the drug will work."

This expectation has been borne out in a study of 58 patients conducted by Mason and his colleagues during the past four years, and reported at a recent meeting of the American Heart Association.

The physicians identified effective drugs in 39 of the patients during laboratory analysis, and prescribed the drugs for the patients when they left the hospital. Effective medications could not be found for the remaining 19 patients, and they were treated on a trial and error basis.

Eighteen months after the laboratory analysis, 82 percent of the patients in the first group were free of arrhythmias, and 73 percent remained free for 50 months.

In comparison, only 22 percent of the second group had not suffered a recurrence of arrhythmias 18 months following the analysis, and 12 months later, that figure had dropped to 11 percent.

Although catheterization involves some risks, the procedure has been conducted with zero mortality, Mason says.

"We believe our method is safer than conventional, trial and error drug testing," he said. "Patients are exposed to arrhythmias anyway until a drug is found that works."

Among other studies conducted at the arrhythmia unit but not yet published is a method for pinpointing the source of a severe or recurrent arrhythmia using electrophysiological techniques, and removing it surgically.

The unit also is conducting basic and clinical research in a variety of areas, such as studying the mechanisms of arrhythmias, testing antiarrhythmic drugs, and developing new types of pacemakers.

One project has resulted in the development of a computerized pacemaker, programmed to identify and to terminate rapid arrhythmias when they occur with electrical pacing stimuli. The device so far has been permanently implanted in four patients, Mason says.

With the help of Dr. James Knutti and his colleagues at the Stanford Center for Integrated Electronics in Medicine, the physicians are studying the transmission of electrical heart signals by radio waves to a receiver outside the body, a process known as biotelemetry.

Basic research is an important part of the arrhythmia unit's work, says Mason, for "the better we understand how arrhythmias occur, the better we can treat or even prevent them."

STANFORD—

Treatment of severe eye diseases and damage caused by acid burns and foreign objects in the eyes are under investigation at Stanford University Medical Center with funds from Research to Prevent Blindness, Inc. (RPB).

RPB, the nation's leading voluntary organization in support of eye research, has provided the Stanford division of ophthalmology with $50,000 in grants over the past 11 years, the organization announced.

Dr. Jules Stein, chairman, said that Stanford is among more than 50 medical institutions receiving annual RPB grant support for the study of eye diseases.

"Scientists at these laboratories are demonstrating the huge potential of research in vision and the critical need for public support of this still under-funded science," he added.

Dr. A. Ralph Rosenthal, head of Stanford's division of ophthalmology, explained that the funds will be used to supplement research in three major projects.

* * * * *

Cytomegalovirus retinitis is a virus infection that frequently appears in patients receiving immunosuppressive (anti-rejection) drugs for organ transplantation, and in patients undergoing chemotherapy for cancer, whose immune system is weakened.

The infection occurs in the retina and may cause blindness, Rosenthal noted.

Dr. Peter Egbert, assistant professor of surgery (ophthamology), has been studying the natural course of the disease, and the ability of doctors to manipulate the condition by altering levels of immunosuppressive therapy.

In addition, in collaboration with Dr. Thomas Merigan, professor of infectious diseases, and Dr. James Gallagher, postdoctoral fellow, he is testing intravenous adenine arabinoside (araA) as a treatment for the disease.

Egbert also is developing photocoagulation techniques that may be used to "wall off" patches of the infection, to keep it from spreading if immunosuppressive therapy must be increased.

Siderosis, an occupational hazard involving iron particles from a foreign body retained in the eye, can cause extensive damage to eye tissues.

Research associate Dr. Sonja Declercq is examining some of the destructive tissue changes caused by the iron, which may be similar to changes occurring in certain retinal degenerative diseases, such as retinitis pigmentosa.

Dr. James McCulley, assistant professor of surgery (ophthamology), is investigating hydrofluoric acid burns in the eye. This chemical, widely used in glass etching and in the electronics industry, causes severe burns of the cornea.

McCulley is examining how the chemical causes cornea damage. It is thought that the fluoride ion may bind other ions in the tissue, depleting those necessary for proper function.

A one day conference on dual career couples in medicine will be held at Stanford University School of Medicine on Sunday, March 9.

Sponsored by the Medical Center's Committee on the Well-Being of Medical Students and House Staff, the workshop will explore issues related to the strains and key decisions that influence dual career couples, with special emphasis on couples where one or both partners are physicians.

The keynote address, by Frank A. Johnson, M.D. and Colleen L. Johnson, Ph.D., both of the University of California in San Francisco, is entitled "Adaptive Strategies to Conflict and Competition in Two-Career Marriages."

Following the address, there will be panel discussions on the subjects of "Early Marriage-Early Career," "Impact of Children on Dual Career Couples," and "Established Marriage-Established Career."

The workshop will be held in Fairchild Auditorium at the Medical Center, from 9 a.m. to 5 p.m..

Pre-registration by March 4 is requested, and the fee for students, residents and Fellows is $8 per individual or $15 for couples. For all others, the fee is $10 for individuals or $18 for couples. Lunch is included and childcare facilities will be available.

For more information, or to pre-register, phone 497-6954.

STANFORD—

Advances in microsurgery, the use of silicone implants, and an altered form of the body's structural protein, collagen, have led to dramatic improvements in plastic and reconstructive surgery.

In the past 15 years, for example, microsurgical techniques have permitted restoration of form and function of body parts ravaged by cancer, according to Dr. Vincent R. Hentz, assistant professor in the division of plastic and reconstructive surgery at Stanford University School of Medicine.

Surgical treatment of cancer can leave grotesque holes in the nose, chest, neck, or side of the face, Hentz said. And while the patient may be "cured" of cancer, "a cure under these circumstances is meaningless," he said.

The "plastic surgical approach" permits immediate reconstruction of the damaged parts, by transfer of tissues and even bones from other areas of the body, and has thereby allowed "even more radical surgery to treat cancer," Hentz said.

Hentz spoke at the second in a series of three Progress in Medicine lectures on plastic and reconstructive surgery Tuesday night, February 19, at the Medical School's Fairchild Auditorium.

Also speaking at the lecture was Dr. Ernest N. Kaplan, associate professor of surgery and chief of the plastic surgery service at Children's Hospital at Stanford.

The lectures, which are open to the public, are sponsored by the School of Medicine.

Tissue transfer is one new technique that has developed with the advent of microsurgery, Hentz said.

Microsurgery refers to the use of the operating microscope and tiny surgical instruments to repair small blood vessels, nerves and tendons.

Blood vessels less than one millimeter in diameter can be sewn together with sutures the size of the thinnest human hair using these techniques, he said.

The most dramatic example of microsurgery is reattachment of severed limbs, including fingers, hands and feet.

Microsurgery also has been employed to correct birth defects, such as absent or webbed fingers. According to Hentz, one out of six infants is born with deformities of the hands or arms.

Surgery can be performed early in life to remove useless parts, such as extra fingers, and to separate fused fingers.

- more -

In addition, a finger or even a toe can be moved to replace an absent thumb and permit the child to grasp objects.

Other examples of plastic and microsurgical techniques include the repair of cleft lips and palates, and reconstruction of missing external ears.

The use of artificial parts has become widespread, particularly in the replacement of diseased hip joints. In addition, silicone, or plastic parts are being used to replace smaller joints such as the knuckles which have been rendered useless by arthritis.

These silicone "hinges" are fitted during surgery into the ends of the bones of the fingers and hand, and can result in a "remarkable improvement in both form and function of the hand," Hentz said.

Recently, a new substance has been developed which is aiding plastic surgeons in repairing so-called "contour defects," depressions in the flesh which result from diseases such as acne.

The substance is collagen, the structural protein of the body, which has been removed from the skin of cattle and chemically and enzymatically treated so that it will not excite immunological rejection when placed in the human body.

This pure collagen is injected as a gel-like liquid under the depressed areas of the skin, where it binds to the natural tissue and eventually forms new skin.

According to Kaplan, several injections of the substance may be required to fill in the depression. The treatment has lasted as long as eight years in the clinical trials performed at Stanford.

The technique for producing pure collagen was developed by four physicians, including Drs. John Daniels and Terry Knapp of Stanford University Medical School. The substance currently is being produced by the Collagen Corporation, a Palo Alto-based firm founded by the researchers, and is being tested by physicians throughout the U.S.

In addition, Kaplan and Hentz and surgery intern Dr. Joseph Rosen have been testing thin layers of collagen as a means of repairing severed nerves in animals.

STANFORD—

A leader in innovative approaches to the diagnosis of tumors, Dr. Sidney Wallace of Houston will deliver the first Etta Kalin Moskowitz Memorial Lecture on Thursday, February 28 at Stanford University School of Medicine.

The talk, entitled "Interventional Radiology in Oncology: Transcatheter Infusion and Occlusion Therapy," will be held at 5 p.m. in room M114 at the Medical Center.

Wallace is professor of radiology and chief of diagnostic radiology at the M.D. Anderson Hospital and Tumor Institute in Houston, one of the leading cancer treatment centers in the United States.

In addition to his formal lecture, which is open to the public, Wallace will present seminars on "Percutaneous needle biopsy and drainage procedures," "Liver masses: CT, ultrasound, and angiographic diagnosis," and "Head and neck tumors: the role of CT and conventional tomography."

The seminars will take place at noon on February 28 and 29 in room S092 in the Medical Center.

A gift from the late Etta Kalin Moskowitz, the purpose of the lectureship is to "provide support for teaching, training and research into the newest developments, techniques, information and advances in diagnostic radiology as it is specifically related to cancer in human beings."

A native of New York City, Mrs. Moskowitz traveled to the West in the early 1930's with her husband, Dr. Simon L. Moskowitz, who established a general medical practice in Brigham City, Utah, in 1935.

A leader in her community's civic and educational organizations throughout her life, she was particularly interested in health affairs and was active in her county and state medical auxiliary, organized the county mental health agency, and was a founding member of her county Red Cross and American Cancer Society programs.

In the early 1960's, following a successful battle against breast cancer, Mrs. Moskowitz focused her interests to fund raising and public education in cancer treatment and research.

Searching for a way to help others with cancer when she was stricken for the second time with cancer, Mrs. Moskowitz established the lectureship shortly before her death in 1978.

It is the first endowed lectureship in the department of radiology.

The second winter Progress in Medicine Lecture on Plastic and Reconstructive Surgery will be held Tuesday, February 19 in Fairchild Auditorium, beginning at 7:30 p.m..

Drs. Vincent Hentz and Ernest Kaplan will discuss "Mending Defects and Injuries: how reconstructive surgeons repair birth deformities and the aftereffects of cancer and trauma."

The lecture is free and open to the public.

Hentz, assistant professor of surgery at Stanford Medical School, is also chief of plastic surgery at the Palo Alto Veterans Administration Medical Center.

A specialist in reconstructive surgery of the upper limbs, Hentz also conducts research on the mechanisms of nerve regeneration and repair.

A graduate of Davidson College in North Carolina, he received his M.D. from the University of Florida in 1968. He joined the staff at Stanford in 1975.

Kaplan is associate professor of surgery at Stanford Medical School and chief of the plastic surgery service at Children's Hospital at Stanford.

He has done research in the field of skin transplantation, and maintains a strong interest in emergency medicine.

Kaplan received both his B.A. and his M.D. from the University of California in Los Angeles.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of Stanford's School of Medicine and by members of the Medical Center Council.

Reconstructing the larynx, or voice box, will be the topic of the fourth annual George S. Kiperash Lecture on Wednesday, February 20, at Stanford University School of Medicine.

The lecture will be delivered by Dr. George A. Sisson, professor and chairman of otolaryngology and maxillofacial surgery at Northwestern University Medical School in Chicago.

The public is invited to the lecture, sponsored by the division of otolaryngology, which begins at 8 p.m. at the Medical School's Fairchild Auditorium.

Sisson is a well known ear, nose and throat specialist who has pioneered techniques for reconstructing the larynx in patients who have had it removed because of cancer.

A graduate of Syracuse University in New York, where he received both his bachelor's degree (1942) and M.D. (1945), Sisson was clinical professor in otolaryngology at Syracuse before going to Northwestern in 1967.

The Kiperash Lecture was established to bring national and international figures to Stanford and to enhance continuing education and residency training.

It is named after George S. Kiperash, Jr., a former Stanford patient and native of San Jose.

Nine junior faculty members at Stanford Medical School have been appointed Agnes Axtell Moule Fellows for the current academic year.

The appointments were announced by Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the medical school.

As Moule Fellows, the nine faculty members will be involved in cancer research. They are Drs. Barbara Carroll, Peter Fessenden, Richard T. Hoppe, Alvaro Martinez and Norman Coleman, radiology; Robert Kessler, surgery; Roger A. Warnke and Jerome S. Burke, pathology; and Branimir I. Sikic, medicine.

The fellowships, which are administered by the Moule Medical Research Foundation, provide support for research and laboratory expenses, some salary support and for travel to scientific meetings.

The Moule Fellowships were established by Manley A. Moule as a memorial to his mother who died of cancer in Palo Alto in 1939.

Moule, a 1917 graduate of Stanford, was involved in real estate with the W. Ross Campbell Co. in Los Angeles. He died in 1974.

Mrs. Moule continues to live in the home Moule built in San Marino 50 years ago.

A refresher course for nurses is being offered at Stanford University Hospital beginning March 5, 1980.

The eight week course entitled "Nursing Update," will be taught Wednesdays from 3:30 to 5 p.m., by Ruth McCracken, R.N., nurse instructor at the College of San Mateo School of Nursing.

Students completing the course will receive 18 hours of continuing education credit.

The course is designed for nurses who are returning to practice after an absence of one or two years.

It covers areas such as the grieving process, pain as a protective response, and how the nurse can help patients return to their normal levels of functioning after an illness.

Registration fees for the course are $33 for hospital employees, and $50 for non-employees. Deadline for registration is Wednesday, February 20, and the class size is limited to 15 students.

Nurses interested in registering for the course, or finding out about other courses should contact Linda Judd in Stanford's Nursing Service office, at (415) 497-5834.

Dr. Thomas C. Merigan has been named George E. and Lucy Becker Professor in Medicine at the Stanford Univeristy School of Medicine.

The endowed chair was recently established by a gift from Dr. and Mrs. George H. Becker of San Francisco, according to Dr. Lawrence G. Crowley, acting vice-president for medical affairs and dean of the School.

The professorship is named in honor of Dr. Becker's late parents, also of San Francisco.

The choice of Dr. Merigan as first holder of the chair is in accord with Dr. and Mrs. Becker's wish that their gift further "the alleviation and prevention of disease."

Dr. Merigan is a leading investigator on the clinical uses and fundamental properties of interferon, a natural body virus-fighting protein.

Studies by Dr. Merigan and his colleagues indicate that interferon is effective against viruses causing shingles, chicken pox, chronic hepatitis B infections, and the common cold.

The substance is also being tested against advanced cancer in a national study supported by the American Cancer Society. Dr. Merigan is co-chairman of that study.

Dr. Merigan was born in 1934 in San Francisco and earned his bachelor's and medical degrees at the University of California.

A member of the Stanford medical faculty since 1963, he is a professor of medicine, head of the Division of Infectious Diseases, and director of the Diagnostic Virology Laboratory at Stanford Hospital.

Dr. Merigan was honored in 1972 with a John Simon Guggenheim Fellowship and in 1973 with the Borden Award for Outstanding Research.

He and his wife Joan, a pediatrician, and son Tom, a student at Woodside Priory, live in Portola Valley.

Dr. Becker, a 1921 graduate of the Stanford University School of Medicine, practiced internal medicine in San Francisco for many years.

He is a diplomate of the American Board of Preventive Medicine and Public Health and a fellow of the Royal Society of Health in Great Britain.

He has served as director of the Bureau of Communicable Diseases of the San Francisco Department of Public Health, vice-president of the Independent Order of Foresters with responsibility for their tuberculosis hospital and aged residents' home, and a member of the Irwin Memorial Blood Bank Commission.

Dr. Becker's many civic activities include leadership in the Tuberculosis Society, Community Chest, American Legion, United Service Organizations (USO), and the San Francisco Young Men's Christian Association (as president during World War II).

He and his wife, the former Miriam Casperson, have been married over fifty years.

STANFORD—

Scientists at Stanford University School of Medicine and SRI International have developed a new drug which enhances the effects of radiation in treating cancer without the serious complications of previous drugs.

The drug, which is called a radiosensitizer, recently was approved for toxicity testing in large animals by the new Drug Development Committee of the National Cancer Institute (NCI).

If the tests are successful, clinical trials in patients could begin within a year, said Dr. J. Martin Brown, associate professor of radiology at the Medical School.

Brown and Dr. William Lee of SRI International in Menlo Park, California, led the team of biologists and chemists which developed the drug. Their work was presented at a recent scientific meeting on radiosensitizers and radioprotectors at Key Biscayne, Florida.

Radiosensitizers refer to certain agents which prevent the ability of cells to repair early damage caused by radiation. The block of repairs leads to death of the cells.

Oxygen is one known radiosensitizer. About 25 years ago, scientists discovered that while normal cells, with normal amounts of oxygen, are killed by radiation, some cancer cells which are hypoxic (lacking in oxygen), survive.

To overcome this problem, clinicians have performed radiation therapy in hyperbaric chambers, attempting to increase the oxygen levels in the resistant cancer cells, and thus improve the effectiveness of radiation.

In addition, techniques using heavy particle radiation (for example, neutron or pi-meson radiation) were developed. Heavy particles can increase the damage done to cancer cells, and the presence or lack of oxygen makes little difference in their effect. However, both heavy particle radiation and hyperbaric techniques are expensive and so far have had only limited success.

Then six years ago, scientists discovered a compound, named misonidazole, which sensitized tumor cells to radiation, without affecting the response of normal cells surrounding the tumor.

"It worked beautifully in animals," Brown said, and clinical trials have begun in Canada, Great Britain, and the U.S..

However, a problem with misonidazole is that it is toxic to nervous tissue in high doses, and therefore is given to patients at only one tenth the strength necessary for a maximum radiosensitizing effect.

In studies supported by the NCI, Brown and Lee found that they could markedly reduce the drug's toxic side effects by modifying it so that it was almost insoluble in fat. The drug was now unable to cross the blood-brain barrier, the fatty wall which separates blood from nervous tissue.

In cell culture studies, and in tests of tumors in mice and spontaneous cancers in dogs, the researchers found that this new drug was as effective as misonidazole in sensitizing cancer cells to radiation killing, but five to 10 times less toxic to nervous tissue.

Now the researchers plan to study the ability of the drug to enhance the effectiveness of chemotherapy, and to act as a cancer-killing agent by itself.

There is evidence that hypoxic cancer cells also may be resistant to chemotherapy, Brown said, and can be sensitized to some anti-cancer drugs in the same way that they are sensitized to radiation.

If this can be proved, then radiosensitizers have the potential for being an even more important development in anti-cancer therapy, he said.

STANFORD—

Stanford University Hospital is offering a $1,000 reward for information leading to the return of the four circuit boards stolen from the radiology department's brain scanner last week.

On February 9, sometime between midnight and 5 a.m., according to Palo Alto police, thieves removed two central processing unit circuit boards and two memory circuit boards from the computer portion of the hospital's EMI brain scanner.

The theft disrupted patient care for nearly 12 hours until temporary replacement parts were obtained from General Electric and installed in the machine.

The stolen circuit boards are not usable except in computers linked to similar scanners, hospital administrators said, and all other agencies and hospitals with similar equipment have been alerted to the theft.

Furthermore, the circuit boards would be difficult to sell outright and are of little value broken into smaller component parts, they added.

Anyone with information about the stolen items is urged to call the hospital at 497-5737.

The reward will be paid upon recovery of the missing items, hospital administrators said.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

CITY DESKS:

You are advised that a new state law, the California Medical Information Confidentiality Act (SB 480) regulating disclosure of medical information became effective Jan. 1, 1980.

The law affects the procedures hospital news services or public relations people must use to release general information about patients to the news media.

This note summarizes the new requirements as they affect the news media so that you will understand why it might take us a bit longer to give you information about a patient, or why we may not be able to give you anything at all.

Section 56.18 of Senate Bill 480 says a hospital may release, at its discretion, information about a patient's name, address, age, sex, reason for admission, general nature of injuries, and general condition, *unless requested not to do so by the patient, next of kin, or the provider of health care.*

We must also tell each patient in no less than eight point type and in a sheet separate from other hospital forms that he or she has the right to request that no information be released, including the fact of hospitalization itself. (That includes public record cases, public officials, everybody).

This means that while we may still release information about patients, we must make sure a specific patient has not requested that the information remain confidential.

In some cases this checking may take us a few minutes longer than usual. We hope this will not create a problem because we will do everything we can to provide the information you need from us in a timely fashion within the confines of the law.

At the same time, you should not be surprised if we are unable to give you the information you need.

The law stipulates clearly if we give you unauthorized information, we will have committed a misdemeanor. The patient whose name appeared in your paper may sue the hosptial for civil damages of up to $3,000, and attorneys fees of up to $1,000 and costs.

So you can see why both you and I better move to Siberia.

Spyros Andreopoulos

P.S. Copy of the law available on request.

STANFORD—

The EMI brain scanner in the radiology department at Stanford University Medical Center is back to normal operation following a $17,000 theft of four circuit boards from its computer Wednesday morning (February 6).

"Fortunately, the disruption in patient care was minimal," said Norman Briggs, administrator in the division of diagnostic radiology.

Although scheduled brain scans for inpatients could not be performed, a General Electric whole body scanner was available in the hospital for emergency use, he said.

Late Wednesday afternoon, about 12 hours after the circuits were first reported missing, replacement parts were obtained from General Electric, enabling normal patient care to be resumed.

General Electric provided the parts from a used EMI scanner stored in a Mountain View warehouse, Briggs said.

New EMI circuit boards are expected to arrive by air today (Thursday) from the east coast manufacturer, he added.

The theft occurred sometime between midnight and 5 a.m. Wednesday morning, according to officer Alan Garcia of the Palo Alto police department.

The matter is under investigation and the police are working on a number of leads involving a possible suspect, he added.

Two central processing unit circuit boards and two memory circuit boards of the computer were taken, Briggs said.

These components form the core of the computer's logic system, he added. The computer processes the scanner's x rays to provide a useful diagnostic image of the brain for physicians.

"It is a highly useful diagnostic tool for many different conditions, including monitoring progress of patients following brain surgery and assessing possible brain damage following injury or stroke," Briggs explained.

Normally, the scanner operates 24 hours per day, seven days a week, and 10 patients or more each day are scheduled for diagnosis.

Following the theft, rescheduling was required for about 10 patients, Briggs said.

The stolen circuit boards are about 20 inches long, 12 inches wide and three-quarters of an inch thick, according to Briggs.

The thief's motive is not known.

Stanford is self insured for thefts up to $25,000, said Robert Beth, director of risk management for the university.

STANFORD—

The high price of silver may force radiologists to move from film to electronics, according to a Stanford University radiologist.

"With the impact of integrated circuit technology and digital electronics, it is becoming feasible to store images electronically rather than on film," said Dr. William Brody, associate professor of radiology and electrical engineering.

The cost of X-ray film at Stanford University School of Medicine has increased 65 percent in the last year, said Norman Briggs, administrator of the diagnostic radiology division, and "we're expecting another 40 percent increase next month alone."

Most of the price hike results from the increase in silver values, which leaped from about six dollars an ounce last January, to $49 per ounce last month. It is now about $36 per ounce.

Briggs said the department of radiology had been spending about $300,000 a year for film and processing costs. This year, that figure is likely to exceed $450,000, he said.

Fortunately, the department has an active silver reclamation program, which enables it to recover between 10 and 20 percent of the costs of film.

Silver washed off the film during processing is collected and sent to a silver refining company in Oakland, which reimburses the department according to the current market price.

In addition, old X-ray films are sold by weight to the firm, or the silver is removed by the department (a process called purging) after the films are no longer needed for patient records, usually after seven years.

"About a year ago, we purged four years' worth of old films, and recovered $55,000," Briggs said. "Now I wish we'd waited another year to do it!"

Because of the reclamation project, and an existing inventory of film purchased when the price was lower, the radiology department has no plans to charge higher fees to patients for X rays, at least in the immediate future, according to department administrator Richard Placone.

"But we may be forced to do so as time goes on," he said.

Other clinics have had similar experiences. Both the Palo Alto and Menlo Medical Clinics recently increased patient fees, partly in response to the increase in X-ray film costs. Higher film costs have also contributed to increased charges in dental offices.

-more-

One solution to the high cost of film would be to reduce the amount of silver it contains. Film companies are actively pursuing this possibility, but so far they have not been able to take all the silver out of film, without losing image quality or increasing exposure time.

Another solution may be to dispense with film altogether. This idea is supported by Dr. William Brody.

Brody is studying the use of digital radiographs to view blood vessels. "Electronics can provide a higher fidelity image of blood vessels than film," he said.

In addition, the new technique is less invasive. To see blood vessels in a conventional X ray, an opaque dye must be injected directly into them from a catheter, or small tube. In comparison, the increased sensitivity of digital radiographs enables physicians to introduce the dye by simple intravenous injection.

Currently, Brody is conducting his studies with a modified CT (computerized tomographic) scanner, a machine which can cost $750,000.

However, there is no reason why the same studies cannot be done on less expensive equipment, specifically designed for electronic radiography, he said.

Although radiographs taken electronically may not be any cheaper than those taken on film, Brody said that storage and retrieval of electronic images could involve considerable savings.

Today, Stanford radiologists store thousands of films in warehouses, and the films must be mailed when medical records are transferred to other physicians. Many films are lost.

With electronics, on the other hand, thousands of images can be stored on a single disc that may cost from six to 40 dollars, and which lasts a lifetime.

In addition, doctors may one day be able to transmit the images to each other over the telephone, or by satellite, Brody said.

Brody predicts the widespread use of electronic radiography in the next five to 20 years. One of the biggest obstacles, however, will be the resistance to change on the part of radiologists.

"Film has served radiologists very well," he said, and it may take economics to get them to look at another system.

STANFORD—

The mission of the Stanford University School of Medicine is to train as many physicians as possible for leadership in scientific medicine, and for careers in research and teaching in all branches of medicine, according to a statement approved by the School's Faculty Senate.

The School provides an educational environment that encourages "intellectual diversity" and offers stimulation and opportunity for self-motivated students interested in developing a "scholarly, investigative approach" to medicine, said the Senate.

This includes studies on the social aspects of disease, health care, and public health policy, as well as bench research and clinical investigation.

Accordingly, the School should select students "who will most benefit from this environment."

In addition, the Senate said, the School has a strong commitment to identify, recruit, and educate women and minority students, recognizing that both groups are underrepresented in the medical profession.

"This underrepresentation is particularly glaring in research and teaching," said Dr. Avram Goldstein, chairman of the Faculty Senate, "and it is precisely here that Stanford can make a special contribution."

Stanford ranked fourth in minority admissions in a survey of medical schools conducted last year by the American Association of Medical Colleges (AAMC), with minority students making up 19.5 percent of total enrollment.

This year that figure climbed to 22 percent.

The Faculty Senate is responsible for admissions, curriculum, and evaluation of candidates for the MD degree.

"Since we are a school of medicine and our graduates will have M.D. degrees, we certainly have the responsibility to ensure that all our graduates are capable of practicing at the forefront—in the leadership—of scientific medicine," said Goldstein at a recent Senate meeting.

"But we don't think that is enough.

"Our principal mission should be to train physicians who will be actively involved in research and teaching in all branches of medicine," he said.

"We believe this principal and rather special mission of this medical school has to be stated explicitly.

"Now we can ask, How can we encourage applications from students interested in teaching, research, and the pursuit of academic medicine?"

The Faculty Senate became concerned about the curriculum in 1978, and two committees were appointed to review it. One committee, headed by Dr. Robert Chase, professor of surgery, called for steps to reaffirm Stanford's original goals, namely—the encouragement of student individuality, the fostering of a graduate approach to medical education, encouragement of interests in academic careers in medicine, and the School's obligation to enlarge the field of knowledge.

A second committee, chaired by Dr. Ruth T. Gross, professor of pediatrics, dealt with problems of student evaluation and recommended the adoption of more rigorous performance standards.

As a result, the Senate now is studying ways of improving the curriculum through the existing committee on courses and curriculum and an ad hoc committee on curriculum evaluation, Goldstein said.

A recommendation by the chairmen of the basic science departments, that students be required to demonstrate competence in each department prior to graduation, is being considered, he said, and "we may end up with even more rigorous requirements" as the curriculum is developed.

STANFORD—

Chronic undernourishment and anemia persist among the thousands of Cambodian refugees in Thailand, but emergency food and medical supplies have improved their situation considerably, according to a Stanford physician who recently visited the refugee camps.

Four months ago, many of the refugees, who streamed across the border into Thailand in the wake of a Vietnamese invasion last year, showed signs of severe malnutrition, said Dr. Dennis Davidson, clinical professor of medicine at Stanford University School of Medicine.

In particular, many children died, and those who survived are small for their age, he said.

Today, however, few deaths occur in the camps because of starvation. The major killers now are malaria and pneumonia.

Davidson estimated that 95 percent of the food and medical supplies which come to Thailand from countries around the world reach the refugees directly.

Yet, despite improved conditions, the need for supplies continues, he said.

Approximately 120,000 people live in two main refugee camps, one located 40 miles from Cambodia, and the other five miles from the border.

In addition, there are an estimated 300,000 to 400,000 refugees camped along the border. Davidson said the medical teams make periodic runs to distribute food and medicine, but there is no consistent way of ensuring the people are getting what they need.

In the two main camps, conditions remain primitive, Davidson said. Families live in cramped, one-room huts made of bamboo or tin with earthen floors.

About 1500 people are seen by medical personnel at the out-patient clinics each day. Seriously ill patients are admitted to one of eight 50-bed hospital wards housed in tents.

There are about 200 medical personnel in each of the camps, but their resources are quite limited. "As I was leaving, one camp was just getting an X-ray machine," Davidson said. "We had to go back to hands-on diagnosis, to feeling comfortable with knowing that you can't be sure what is wrong before you begin treatment.

"There is a danger of being immobilized by this uncertainty," he added. "If you wait too long before beginning treatment, your patient won't survive."

Davidson spent three weeks in the camps in December, working as a relief physician with a Dutch medical team in the outpatient clinics. He went to Thailand on his own, using his own money to pay for the trip, but said it is easier to join the relief effort as a member of a sponsored medical team.

Davidson, who works with the Stanford Heart Disease Prevention and Rehabilitation Programs, is not a newcomer to this kind of experience. While still in medical school, he worked in clinics in Madagascar for a month. In 1975, while in the Navy, he was in charge of the medical aspects of the Southeast Asian refugee camps at Camp Pendleton in California.

He said his experiences help him keep the sophisticated technology of medicine in the U.S. in perspective. "The majority of the world's population has very primitive medical care by our standards," he said.

Davidson said he was most impressed by the wide variety of nationalities represented in the relief efforts in Thailand. In a day when international tensions were high, "it was nice to see the United Nations banner flying over the camps," he said.

STANFORD—

The many aesthetic benefits and medical applications of plastic and reconstructive surgery will be discussed by five prominent physicians in the winter Progress in Medicine Lecture series sponsored by Stanford University School of Medicine.

Scheduled for three successive Tuesday evenings in February, the series, entitled "Face and Form," will be held in Fairchild Auditorium at the medical center. All lectures are open to the public and will begin at 7:30 p.m..

February 12—Art and Science: an overview of the development of plastic surgery, with Dr. Robert A. Chase, Emile Holman Professor of Surgery, in Stanford's division of plastic and reconstructive surgery.

February 19—Mending Defects and Injuries: how reconstructive surgeons repair birth deformities and the aftereffects of cancer and trauma, with Dr. Vincent Hentz, assistant professor of surgery, and Dr. Ernest Kaplan, associate professor of surgery, both of Stanford's division of plastic and reconstructive surgery.

February 26—Mirror, Mirror: aesthetic surgery to redesign the face, breast, and other features, with Dr. Donald R. Laub of the Palo Alto Medical Clinic (formerly associate professor and chief, division of plastic and reconstructive surgery), and Dr. Lars M. Vistnes, associate professor of surgery and chief of the surgical service at the Palo Alto Veterans Administration Medical Center.

The Progress in Medicine Lectures are presented as a community service by the dean and faculty of Stanford's School of Medicine and by members of the Medical Center Council.

STANFORD—

In a carefully planned but risky airborne transport operation lasting over 14 hours and covering more than 6,000 miles, an intensive care nurse and doctor from Stanford University Hospital successfully escorted a critically ill Englishman home to a London hospital last week.

With a series of traumas in his recent medical history, including a stroke, severe pneumonia, cardiac arrhythmia and a heart attack, Harry Humphreys was a very sick man, requiring the most comprehensive intensive care Stanford Hospital could provide, according to his intensive care unit physician, Dr. Thomas Feeley.

"Taking Mr. Humphreys back home to England was the one thing he needed beyond the best medical care we were able to provide," Feeley said, explaining the plight of the 70 year old Humphreys, who had been in the hospital for more than three months.

Dr. Alvin Hackel, associate professor of clinical anesthesia and pediatrics at Stanford, and director of the Stanford Critical Care Transport Service, supervised the transport arrangements.

(The Stanford Critical Care Transport Service transfers critically ill patients in referring community hospitals to and from Stanford while providing ongoing intensive care. It is run in tandem with the Northern California Infant Medical Dispatch Center, which locates intensive care nursery beds for critically ill babies, and assists in arranging transport of the babies from any of 120 participating community hospitals to 20 intensive care and intermediate intensive care nurseries in northern California.)

"A patient as sick as Mr. Humphreys is an unusual case for such a long transport, but under the appropriate circumstances we are prepared to carry out this kind of service," Hackel said.

"The care Mr. Humphreys received on the flight was equivalent to the level of care he was getting here in the hospital," he explained.

Humphreys entered Stanford Hospital over three months ago, following a stroke he suffered while on vacation visiting friends in the Bay Area with his wife, Alice.

According to Feeley, when the idea of going home to England was first suggested to Humphreys by several nurses taking care of him, he eagerly embraced the idea.

His wife, who was with him constantly during his hospitalization, recalled that "he was a changed man."

Although Humphreys suffered a dangerous cardiac arrhythmia the morning before the scheduled transport, his wife and daughter felt the risk of transport was still worth getting him home, Feeley recalled.

"In fact, the added risks probably helped ensure that we were prepared for any complication," Feeley said.

-more -

Feeley and intensive care nurse Sherry Moore spent nearly 24 hours tending Humphreys, in the ambulance from Stanford Hospital to the San Francisco Airport where they boarded a Pan American airways 747; on board the plane for almost 14 hours until arrival at London's Heathrow airport; and on the British National Health Service ambulance which finally brought Humphreys to his destination, St. Thomas' Hospital in London.

"The entire operation went incredibly smoothly," Feeley said, recalling the planning that went into the effort.

The airplane was specially prepared, with a group of seats removed from the center section so that Humphreys' stretcher could be accommodated, and so that the necessary cardiac monitor, defibrillator, oxygen tanks, and other equipment could be stored.

A special electrical inverter was also installed in the plane, to provide the necessary power for the equipment.

Feeley had consulted with doctors at St. Thomas' Hospital, as well as with the ambulance crew, paramedics, and airport and airline personnel at Heathrow, so that all were ready and waiting for Humphreys' arrival.

Only one problem arose when they discovered that the hospital ward where Humphreys was expected did not have appropriate intensive care facilities, said Feeley.

However, temporary arrangements were made for his overnight monitoring and care, and the following day Humphreys made one final move to St. Thomas' intensive care ward in central London.

Several days after his return to England, Humphreys was sitting up in bed for three hours at a time, longer than had been possible in many weeks, Feeley reported recently from his office at Stanford, after talking with Humphreys' daughter, Yvonne, on the phone.

"His chances now for returning to a good life at home are high," commented Feeley.

In addition to Feeley and Moore, many individuals helped coordinate the transport, according to Hackel, including an anonymous donor who paid for the airline fares; Tricia Robertson of the Dispatch Center; Reverend Ernie Young, Chaplain at Stanford Hospital; Jean Harman of European World Travel; Frank Quigley of Pan American Airlines; and Dr. Jan Ehrenwerth, associate director of the transport service.

Although such medical air transports are not routine in the United States, they are quite common in Europe, Hackel noted. One transport insurance plan in France has over ten million subscribers, he added.

STANFORD—

"This will open up a whole new world for the deaf and the speech impaired," commented Shari Creley as she prepared the portable machine for a transmission.

The "machine" is a specially-designed device that resembles an adding machine (is about the same size as a portable typewriter, and weighs about five pounds) that allows deaf people to transmit and receive typed messages.

Stanford University Hospital currently has two of the machines (trademark name is "Portaprinter"), and eventually will have three, estimated Creley, who is an administrative assistant in the hospital's Department of Facilities and a member of the advisory committee on the disabled for the medical center.

Hospitals are now required to have the machines for emergency communications for the deaf, and in addition to Stanford a machine is in use at Santa Clara Valley Medical Center in San Jose. (Santa Clara Valley is affiliated with Stanford Medical School).

The machines hook up to any telephone, Creley explained, and for in-house hospital patients a "signalman" relay can be rigged so that a bedside lamp will flicker when an incoming transmission is about to begin.

"One of the great things, though, is that deaf people can call us with this device if they need emergency medical attention," Creley added, "this is a big step for them."

Stanford has notified a variety of state and national agencies that it now has the machines available for its deaf patients.

Eventually, she said, the machines will probably be maintained in Department of Emergency Services, Stanford Medical Center Communications and the hospital's ENT Clinic.

Officials estimate that over 800 deaf people already have the special machines in their homes in Santa Clara County.

STANFORD—

Dr. Ira H. Pastan will present the seventh annual Windsor C. Cutting Lecture Thursday, Feb. 7, at Stanford University School of Medicine.

The lecture is open to the public and begins at 4:15 p.m. in the medical school's Fairchild Auditorium.

Pastan is chief of the Laboratory of Molecular Biology at the National Cancer Institute in Bethesda, Md. His talk is entitled "Watching Hormones Act by Video Intensification Microscopy."

He was awarded the Van Meter Prize of the Amrican Thyroid Association in 1971, and he has used new methods to study the mechanism by which polypeptide hormones like insulin move to the interior of cells.

When insulin or other peptide hormones are made to fluoresce he has been able to follow their movement using an image-intensifier television camera.

Pastan's work is considered another step towards understanding how these hormones influence the function of the cells and thus exert their important physiological effect to combat diseases such as diabetes.

Pastan received his M.D. from Tufts University and worked in the field of endorcine biochemistry at the National Institute for Arthritis and Metabolic Diseases before joining the staff of the National Cancer Institute.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology at Stanford Medical School, and is supported by private contributions.

It honors the late profession and former department chairman by featuring speakers prominent in the pharmacology field.

Cutting, who died in 1972, also served as dean of the medical school during 1953-57, and as dean of the University of Hawaii Medical School during 1963-71.

STANFORD—

Several Stanford University physicians have resigned from the department of surgery at Santa Clara Valley Medical Center in San Jose.

The resignations resulted from a dispute with Santa Clara County, which administers the Medical Center, over salaries and the manner in which fees generated by the department are used, according to Dr. John Collins, professor and chairman of surgery at Stanford Medical School.

Currently, the County is negotiating with the surgeons, who want more of the fees made available for education and teaching purposes, said Collins.

All of the resignations are not necessarily final, he added.

At the same time, the Medical School has formed a committee headed by Acting Dean Dr. Lawrence Crowley, to look into the long-range aspects of the Stanford-Valley relationship.

"The purpose of the committee is to see if a more stable and mutually beneficial relationship can be constructed," Collins said.

Valley Medical Center has had a long-standing affiliation agreement with Stanford Medical School.

Under the agreement, Stanford provides staff for various services at Valley including surgery, medicine, pediatrics, and gynecology and obstetrics, as part of the teaching program of house staff and medical students.

However, problems have resulted from the uncertain future of Valley Medical Center, and from ambiguities in the status of Stanford faculty physicians who are assigned there, Collins said.

"It is probably an appropriate time to redefine the Stanford-Valley relationship," he said. The County faces a significant decision about renovating the Medical Center, Collins explained, and there are concerns about what will happen if the proposed Jarvis II initiative passes.

Collins said he was optimistic that the County and the Stanford surgeons would arrive at a mutually satisfactory solution through the negotiations.

STANFORD—

A technique for treating cancers of the lymphoid system shows promise in preventing rejection of transplanted organs and in relieving pain and inflammation of rheumatoid arthritis, according to a Stanford University immunologist.

"We find that we can use this technique as a method of 'immunological engineering,' " said Dr. Samuel Strober, associate professor of medicine and chief of the division of immunology at Stanford University School of Medicine.

The technique, called total lymphoid irradiation (TLI), refers to high dose radiation of the lymphoid tissue of the body—lymph nodes of the neck, chest and abdomen, thymus gland, and spleen. Other radiosensitive areas, including the head, lungs and limbs, are protected from radiation.

Already TLI has been used by the renal transplant team at the University of Minnesota with a "striking improvement" in the survival of kidneys transplanted into high risk patients who already had rejected a prior kidney, Strober said.

In addition, Strober and his colleagues have treated five patients who were disabled by rheumatoid arthritis and who did not respond to any other conventional treatment, with 2,000 rads of radiation each to the chest and abdominal lymphoid regions.

All patients have responded, he said. One woman who previously was wheelchair-bound and in almost constant pain is now essentially pain free, ambulatory, and able to perform her household chores.

Strober reported the technique Friday, March 28, during the scientific symposium at Stanford Medical School honoring the 20th anniversary of the School's move to the Stanford campus.

TLI is a technique developed over 15 years ago by Dr. Henry S. Kaplan, Maureen Lyles D'Ambrogio Professor of Radiology at Stanford, to treat Hodgkin's disease and other cancers of the lymphoid tissues.

The treatment has helped to improve the cure rate of early stage Hodgkin's disease from only 30 percent in the 1960s, to 86 percent today.

TLI causes a profound and prolonged drop in the lymphocytes, white blood cells responsible for the body's immune responses, including the defense against infection. Yet, less than one percent of the Hodgkin's patients treated with TLI contract severe bacteriological infections requiring hospitalization.

In addition, none of the several hundred patients treated with high dose radiation in this manner over the past 10 years has developed leukemia, Strober said.

In studying these patients, Strober said he and Kaplan "were impressed by the very significant immune deficits in these patients," which were similar to those of patients who received immunosuppressive drugs, including corticosteroids, to prevent rejection of transplanted hearts.

- more -

Yet, unlike the cancer patients, the heart transplant patients were exquisitely susceptible to infection. In fact, raging, uncontrollable infection is the major cause of death among heart transplant recipients today.

This suggested that TLI could improve the success rate of organ transplantation.

First in mice, then in rats, Strober and his colleagues found that TLI permitted them to transplant bone marrow, skin, and even hearts from unrelated donors without rejection, even when the animals had received no other form of immunosuppression.

The skin and heart grafts were taken from the same donor as the bone marrow, suggesting that the donated lymphoid tissue in the marrow had paralyzed the host's immune system and that the host accepted what otherwise would have been considered foreign skin and heart tissue.

In addition, the animals did not exhibit what is called the "graft versus host" reaction, in which the donor white blood cells attack the host.

TLI apparently had induced "mutual tolerance" of donor to host and host to donor, Strober said.

To explain this phenomenon, Strober's colleague Dr. Donna King found that TLI resulted in the development of a certain population of lymphocytes, called suppressor cells, which prevent immunological attack of either donor or host cells against each other.

This could also explain how TLI improves rheumatoid arthritis, by correcting a deficit of suppressor cells which is thought to underlie certain "auto-immune" diseases. The reduced level of suppressor cells allows other types of lymphocytes to attack the body causing inflammation, pain and eventual destruction of tissues.

Another of Strober's colleagues, Dr. Brian Kotzin, confirmed this effect of TLI in mice with an auto-immune disease, before beginning tests in humans with disabling rheumatoid arthritis.

One of the most gratifying aspects of the treatment, Strober said, is that it enabled patients to discontinue their chronic use of high levels of potentially addicting pain killers such as codeine, to reduce or eliminate the corticosteroids they were taking, and to rely solely on minimal doses of aspirin as their only maintenance drug.

In addition to the arthritis studies, Strober's group, in association with the Stanford cardiac transplant team, is now testing the effect of TLI on heart transplants in dogs and monkeys.

The researchers also plan to test TLI in low risk patients who are receiving a first kidney transplant, with the kidney transplant team at the University of California at San Francisco, "in an attempt to completely eliminate corticosteroids from their immunosuppressive regimen."

Strober said the application of TLI is very broad. In addition to organ transplantation and treatment of auto-immune diseases, the technique may be important in bone marrow transplantation.

Currently, bone marrow transplants for treatment of aplastic anemia or leukemia can be taken only from matched donors such as a twin brother or sister, or else the graft will be rejected.

TLI might enable successful bone marrow transplantation even from unmatched donors, Strober said.

CITY DESKS: Stanford University School of Medicine celebrates the 20th Anniversary of its move from San Francisco to Palo Alto, with a two-day scientific symposium March 27 and 28 in Fairchild Auditorium. The symposium highlights the School's scientific contributions in the fields of genetics, molecular biology, and clinical medicine. This background story of the history of the move and the School's accomplishments supplements an earlier story about the symposium.

STANFORD—

"Medicine for a new age."

With these words Dr. Frank Stanton, the president of CBS, dedicated the new Stanford University Medical Center on the Stanford campus September 18, 1959.

His speech was fitting, because more than just the buildings were new. The School had a new curriculum, strengthened faculty, and revitalized spirit.

"It was the beginning of the most significant venture to humanity at Stanford since the founding of the University itself," said then Stanford University President J.E. Wallace Sterling.

The School of Medicine had been located in San Francisco, where all clinical and some basic science teaching took place for 50 years. Recognizing that medical education is a responsibility of the University, Stanford during Sterling's presidency undertook the planning for the School's move to the campus.

"The opening of the Center, with its school and laboratories, and new Hospital and Clinics, occurred at a time of great ferment and growth in biomedical research," recalls Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean.

"A national commitment had been made to accelerate biomedical research. Stanford joined in that commitment."

From the start, adds Crowley, the School decided that future doctors could best be trained in an atmosphere of research, and that such an environment would attract the most capable faculty to teach them.

Dr. Robert H. Alway, former dean who presided over the move of the School, had declared at the time, "Only through exposure to teachers who manifest the scientific approach can we minimize the human tendency to take the easy way, embracing empiricism and dogma."

There should be no basic difference between the scientist and the practicing doctor, Alway added. "Both share the same attitude that they are trained to observe, to reflect, to draw tentative conclusions."

"It is in this spirit that teaching, research, and patient care have evolved here," says Crowley. "Research, both basic and clinical have flourished. The School has made impressive contributions."

- more -

In 1959, unlike most medical schools who taught their students on indigent patients in county hospitals, Stanford was faced with the necessity of operating its teaching programs in a hospital whose patients, because of the socioeconomic characteristics of Palo Alto and Santa Clara County, would be private in the traditional sense.

"There were many," recalls Crowley, "who believed that the School could not carry out a satisfactory program under such circumstances, and who predicted disastrous consequences for Stanford's program in medicine."

The events of the past 20 years speak for themselves, he points out. The School has attracted a superb group of academically-oriented physicians. The ability of the group has been demonstrated by the development of many outstanding clinical programs. The faculty medical practice increased from 13,000 patient visits per year in 1959 to over 130,000 patient visits in 1979.

The faculty is also responsible for nearly half of the 24,000 admissions to Stanford University Hospital. The Hospital also serves as a community hospital for some 400 practicing physicians, many of whom teach as members of the voluntary clinical faculty.

The quality of the teaching programs, instituted and operated with private patients, is attested to at least in part by these criteria, according to Crowley:

- The outstanding quality of Stanford students, and the excellent record of Stanford graduates in obtaining the most competitive internships in the nation's leading hospitals.
- The attraction of the internship and residency programs offered on the several Stanford clinical services for the top graduates of leading institutions from all parts of the country.
- The leadership of Stanford in innovations from both basic and clinical research, and the number of its graduates (more than 20 percent) who choose to enter careers in research and academic medicine.
- The active participation of many community physicians in teaching as members of the voluntary faculty.

Among Stanford's research achievements during the two decades, Crowley listed:

- DNA, the primary genetic material of living things, was brought to clear understanding.
- The techniques of transplanting genes from one species to another were developed, paving the way for studies of the organization of complex animal chromosomes in ways not possible previously.
- The same techniques have ushered a new era of genetic engineering, enabling construction of "bacterial factories" that will synthesize a variety of biologically produced substances such as hormones.

- more -

- The first fully successful complete replacement of the heart in animals was achieved in 1960. It provided the model in which the surgical techniques could be standardized, and diagnosis and treatment of rejection developed. Now the survival of heart transplant patients is equal or superior to that of recipients of kidney transplants.
- The first linear accelerator for cancer treatment in the Western hemisphere was built, leading to modern radiation therapies for Hodgkin's disease and other forms of cancer.
- A technique to isolate the clotting factor lacking in the blood of hemophiliacs was developed, leading to a treatment now used throughout the world for control of the disease.
- A little known protein molecule called the human leukocyte antigen (HLA) has been studied, leading to an understanding of why certain genes that protect man from germs also leave him susceptible to diseases such as rheumatoid arthritis.
- Another finding that the brain has its own opiate receptors, and that it produces its own opiates now provide a major challenge to learn what role they play in brain function and behavioral disturbances.

Many other "space-age" tools for diagnosis and research were developed and are in use in medical institutions. The most dramatic of these is the fluorescence-activated cell sorter. This tool is capable of identifying and isolating closely related types of animal cells at rates of up to 5,000 cells per second—a boon to research in cell biology, diagnosis and treatment of genetic defects, and disorders of the immune system.

It is estimated that many of the inventions at the University have come from the School of Medicine or from joint collaboration with the School of Engineering and other University departments.

Looking back to the time when Dr. Stanton delivered his speech, "Medicine for a New Age," one could not have anticipated the developments of the past 20 years, Crowley says. "The School has thrived and prospered from the close association with the many disciplines of the University, and has contributed significantly to the health and the intellectual life of the University, and the local and national community."

STANFORD UNIVERSITY MEDICAL CENTER

News Bureau Stanford, California 94305

CITY DESKS: This year marks the 20th anniversary of the move of the Stanford University School of Medicine from San Francisco to the main campus in Palo Alto. The event will be celebrated Thursday and Friday (March 27, 28) with a scientific symposium in Fairchild Auditorium. This historical background and facts and figures supplement stories sent out earlier.

STANFORD—

This year marks the twentieth anniversary of the dedication of the Stanford University Medical Center on the campus of Stanford University.

Designed by architect Edward Durell Stone, the inter-connected building complex provided a new home for the School and its Hospital and clinics.

Construction began in 1957 with the excavation for the Palo Alto-Stanford Hospital. The first Hospital patients were admitted in August 1959, and medical school classes began the following month.

The Hospital has a unique relationship with the City of Palo Alto in that it serves as the community hospital of more than 400 community physicians and their patients. Many of these physicians also teach as members of the voluntary faculty.

The School of Medicine was originally Cooper Medical College, which was incorporated in 1882 as a successor to earlier schools established in San Francisco by the University of the Pacific.

The Cooper properties were transferred to Stanford University ownership in 1908, and all clinical and some basic science teaching took place in San Francisco for 50 years.

In 1953, recognizing that medical education is a responsibility of the University, Stanford undertook the planning for the move of the School to the main campus, culminating in the dedication of the Medical Center in 1959.

Facts for 1979 about the Stanford University Medical Center follow:

Stanford University Hospital	
Admissions: 23,028 Days of care:	165,330
Emergency Department census:	28,219
Personnel, including part-time:	3,870
Interns and residents:	396
Budget:	$91 million
Outpatient visits:	130,218
Stanford University School of Medicine	
M.D. candidates, all classes:	380
Advance degree candidates (non-M.D.)	166
Postdoctoral scholars:	331
Total faculty:	458
Volunteer clinical faculty:	1,355
Budget (including $34 million in sponsored research):	$80 million
Affiliated institutions:	
Children's Hospital at Stanford	
Santa Clara Valley Medical Center	
Veterans Administration Medical Center, Palo Alto

STANFORD—Dr. Lawrence G. Crowley, acting vice-president and dean of the Stanford University School of Medicine for the past 15 months, has asked to be relieved of his present administrative responsibilities effective August 31, 1980.

In a letter to Stanford University President Richard W. Lyman, Crowley said that although progress had been made in the solution of many of the problems that he inherited at the end of 1978, many short- and long-range issues and problems face the Medical Center in the immediate months ahead.

"I believe the latter must be properly and resolutely addressed by someone in a confirmed leadership role rather than by an individual in a continuing acting capacity," Crowley wrote.

Crowley said he is willing to remain as a vice-presidential candidate and will continue to function vigorously in an acting capacity in the immediate months ahead.

"After September 1, 1980, I would like to return to my normal academic duties," he added.

The University is conducting a nationwide search for a vice-president for medical affairs to head the multimillion-dollar Medical Center. Its previous vice-president and dean, Dr. Clayton Rich, resigned in 1978.

Speaking for Lyman, who is out of town, Donald Kennedy, Stanford vice-president and provost said:

"Dr. Crowley has given us very dedicated and effective service as vice-president in the past 15 months. Anyone who has served in an acting capacity in a large organization recognizes it is difficult to do so for so prolonged a period."

Crowley undertook a two-year effort to close large projected deficits with the result that the School ended in the black in 1979, and with future projected deficits in a controllable range.

He settled an outstanding issue over reimbursement with the state's Medi-Cal program, formed a liaison committee of faculty and community physicians to develop recommendations for solving town-gown relationships, launched a planning process to correct building deficiencies in the Hospital, and a long-range study to determine future academic and building priorities for the Medical School.

In addition, he helped develop closer ties with Children's Hospital at Stanford. This allowed for the move of the entire department of pediatrics outpatient clinics to Children's Hospital, a major step toward creating a true children's medical center located at Stanford.

"Acting leadership may have been satisfactory in the past," wrote Crowley, "but because of intense national interest in health manpower education and biomedical research, as well as the major concern about the cost of health-care delivery, academic medical centers are functioning under intense scrutiny in a very dynamic, fast-moving public arena.

"Sound, stable leadership is essential, with ability to act promptly and decisively in order to provide an opportunity for the Center to survive and continue as a leading university medical center."

Except for a period in which he served as dean of the University of Wisconsin Medical School in Madison, Crowley, 60, has been associated with Stanford since 1964 as a professor of surgery, associate dean, and deputy dean. He was chief of surgery at the Palo Alto Veterans Administration Hospital, and was instrumental in developing an effective clinical teaching service.

He holds the M.D. from Yale. Prior to coming to Stanford he was a member of the faculty at Yale and the University of Southern California and was in private practice in Los Angeles.

STANFORD—

A term professorship in spinal cord injury medicine is being funded at Stanford University School of Medicine, by a $260,000 five-year grant by the Paralyzed Veterans of America (PVA).

Mr. Joseph Romagnano, national president of PVA, presented the grant to Stanford University President Richard W. Lyman and Dr. Lawrence G. Crowley, acting dean of the Medical School, during a luncheon March 20 at the Stanford Faculty Club.

"We are very grateful to the Paralyzed Veterans of America for their generous support of this program," said Crowley.

Crowley said the money will be used to support the teaching, research, and clinical activities of the chair holder, who has not yet been named.

According to Edward Jasper, executive director of the Bay area and Western chapter of the PVA, Stanford is the first U.S. medical school to have a chair in spinal cord injury medicine.

"We hope to obtain full endowment for the professorship in the future," he added.

The chair adds to already existing programs in spinal cord injury medicine and axonal disease research directed by Stanford faculty members and based at the Palo Alto Veterans Administration Medical Center.

In addition to supporting research, Romagnano said the purpose of the PVA grant is to encourage the recognition and certification of spinal cord injury medicine as a specialty by the American Medical Association.

"There are too few doctors adequately trained in the problems of patients with spinal cord injuries," he said. Getting more doctors involved in the field has been a goal of the PVA for the past 28 years.

The PVA was established in 1946, and was chartered by Congress in 1971.

The organization has donated over one million dollars to spinal cord injury research, and currently is supporting legislation in Congress which would increase funding of the spinal cord injury program of the National Institutes of Health to $16 million a year, Romagnano said.

"A lot has been done in maintenance, in keeping us alive," he said. "But until recently, support of research on nerve regeneration, for example, was quite limited."

STANFORD—

In a successful cost containment effort, Stanford University Hospital saved almost half a million dollars in medical supplies between July, 1978 and November, 1979.

The savings were achieved through the efforts of a Product Evaluation Committee, established to help standardize patient care supplies and equipment used in the Hospital, according to John Rettig, director of the Hospital's materials management program.

"Standardizing to a single product brings a direct cost benefit since the manufacturer's price often depends on the quantities of the product sold," said Rettig.

By standardizing 14 different patient care supplies, $461,000 was saved, he said.

There is also a direct enhancement of patient care from standardizing supplies, Rettig added.

"The same product is available throughout the Hospital, and staff are familiar with the items and how to use them. There are no unexpected surprises waiting on the shelf," he noted.

The money saved will enable the Hospital to keep prices lower for these items, according to assistant administrator, William Arnold.

Some products involved in the recent savings include intravenous solution, electrodes, needles and syringes, endotrachial tubes and shoe covers used by operating room staff.

The Committee screens products according to specifications provided by each Hospital department using the item.

Samples are tested and evaluated by the departments, and the manufacturer who presents a satisfactory product and the most economical bid is selected, Rettig said.

"A good contract is highly desirable, and should include a low price and a protective inflation clause covering several years," he added.

The Product Evaluation Committee coordinates the selection process and has representatives from the medical staff, nursing staff, infection control, clinical laboratories, operating rooms, clinical engineering, clinics, and other Hospital departments.

Rettig expects further substantial savings from the Committee's continuing activities.

City Desks: Because of the limited seating capacity of Fairchild Auditorium, the Stanford Medical School 20th Anniversary scientific symposium can be attended by invitation only. However, members of the press wishing to cover the meeting are welcome. Invitations and advance programs have been mailed to science writers.

STANFORD—

A scientific symposium, celebrating the 20th Anniversary of the move of Stanford University School of Medicine from San Francisco to Palo Alto, will be held March 27 and 28 in Fairchild Auditorium.

It was September 1959 when the new Stanford Univeristy Medical Center complex, consisting of a hospital, clinics, and Medical School classrooms and laboratories, was dedicated on campus.

At the time Stanford University president J. E. Wallace Sterling called the move "the beginning of the most significant venture in service to humanity since the dedication of the University itself . . ."

The symposium, organized by the faculty under the chairmanship of Nobel Laureate Arthur Kornberg, takes place as the School enters a new decade. The presentations try to recognize the scientific contributions of the faculty during the last 20 years, according to Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the School of Medicine.

Because of limited seating capacity in Fairchild Auditorium, the symposium is open to invited guests, and to members of the campus community.

The morning session Thursday, March 27, from 9 a.m. to 12:15 p.m. will be on the topic of "Genes and Chromosomes" with David Baltimore, American Cancer Society professor of microbiology at the Massachusetts Institute of Technology, as guest commentator.

The talks include: "DNA Replication" by Arthur Kornberg; "A Molecular View of Chromosomes" by David S. Hogness; "Transplanting and Manipulating Genes in Bacteria" by Stanley Cohen; and "Transplanting Genes into Mammalian Cells" by Paul Berg.

The afternoon session from 2 to 5 p.m. will cover advances in "Neuroscience" with Nobel Laureate F. H. C. Crick, of the Salk Institute, as guest commentator.

The talks include: "Neurophysiology and Pathology of Sleep" by William C. Dement; "Generation of the Visual Signal in the Vertebrate Eye" by Denis A. Baylor; "Nerve Growth Factor" by Eric M. Shooter; and "Endorphins: Natural Opiates of the Brain" by Avram Goldstein.

-more-

The morning session Friday, March 28 from 9 a.m. to 12:15 p.m. will be on "Immunology and Genetics" with Walter Bodmer, director of the Imperial Cancer Research Fund, London, England, as guest commentator.

The presentations include: "Genetics and Culture" by Luigi Cavalli-Sforza; "Monoclonal Antibodies and the Fluorescence-Activated Cell Sorter" by Leonard A. Herzenberg; "Genes, Antibodies and Disease: The Hidden Cost of Survival of the Fittest" by Hugh O. McDevitt; and "Dynamics of Antibodies and Other Receptor Proteins" by Lubert Stryer.

The afternoon program, from 2 to 5 p.m., will feature "Conquest of Disease at the Clinical Level" with Joshua Lederberg, Nobel Laureate, and now president of Rockefeller University, as guest commentator.

The presentations are "Hodgkin's Disease: Hope Replaces Doom" by Henry S. Kaplan; "Antivirals as Therapeutic Agents" by Thomas C. Merigan; "Transplantation of the Heart" by Norman E. Shumway; and "Total Lymphoid Irradiation in Organ Transplantation" by Samuel Strober.

The Stanford University School of Medicine, said Crowley, moved to the main Stanford campus at a time of great ferment and growth in biomedical research.

"In the short span of twenty years the Medical School with a small faculty and student body, has made singular contributions to the advancement of medicine and biology, with revolutionary findings leading to a new understanding of disease, and ways of coping with it," he said.

The Stanford Medical School was originally a private school, Cooper Medical College, which had been incorporated in 1882, the successor of earlier schools established in San Francisco by Dr. Samuel Elias Cooper and Dr. Levi Cooper Lane as part of the University of the Pacific.

In 1908 Cooper Medical College became the Stanford University School of Medicine and thrived in San Francisco as a school with a rich clinical tradition.

In 1953, deciding that medical education is a central responsibility of the University, Stanford, under the presidency of Dr. Sterling, began plans to relocate the School from San Francisco to the main campus, culminating in the dedication of the Medical Center in 1959.

EDITORS: This announcement is being released simultaneously by Stanford University and the University of California, San Francisco.

STANFORD—

An unusual program that trains young physicians in non-biological disciplines related to medicine and health affairs recently received funding for a three-year period at Stanford University Medical School and the Univeristy of California - San Francisco School of Medicine.

A joint training program with faculty from the two schools and from UC Berkeley, the Clinical Scholars Program is funded by the Robert Wood Johnson Foundation of Princeton, New Jersey.

The Foundation recently approved a $925,288 grant for three years to continue the program, now in its sixth year. There are currently nine scholars, four at Stanford and five at UC.

The program allows physicians who are committed to clinical medicine the opportunity for broader training in such fields as health care delivery, clinical decision-making, medical practice and public policy in health, according to the Foundation.

During the two-year program, scholars work together in a series of seminars and individually on special projects with faculty advisors.

The faculty members contribute expertise in fields such as epidemiology, biostatistics, medical information sciences, economics, sociology, anthropology, law and ethics, and the management sciences of accounting, systems analysis, operations research, and cost-benefit analysis.

According to Dr. Halsted Holman, professor of medicine and director of the Stanford portion of the program, most of the physicians are interested primarily in the areas of organization of health care, medical sociology and economics, and medical education.

"Introducing non-biological disciplines into medical thinking and practice will not by itself resolve the problems in health care . . . nonetheless these disciplines can yield understandings and methods which can greatly enrich and facilitate the search for better solutions," Holman said.

Factors affecting patients' return to work following major cardiac illness and cardiac surgery is the topic of one Stanford scholar's research.

Another Stanford scholar is trying to develop practical methods of assisting physicians with ethical decisions in medical practice.

Presently, seven Clinical Scholars training programs are funded by the Foundation.

Twenty-eight physicians have completed training in the Stanford-UC joint program.

Former scholars are involved in academic medicine, government, and in the practice of medicine, according to the Foundation.

They are developing and managing health care institutions and delivery systems, working in a variety of public and private institutions, and a number are contributing to the formulation, conduct and evaluation of health-related public policy.

Editors: Photo of Preston available if not included with release

STANFORD—

John Preston, a counselor at Stanford University's Help Center and an education training assistant and social worker at the Rehabilitation Engineering Center at Children's Hospital, considers himself a lucky man in many ways.

"There are few people who have the opportunity to use all the skills they have learned in school in a satisfying career, but I happen to be one of them," he says with an immensely appealing smile.

Preston uses his counseling skills at the Help Center and his business administration background and marketing skills in evaluating controls and devices for disabled children at Children's Hospital.

But he brings much more than school learning to both jobs—he shares openly and warmly his personal experiences as a disabled person.

Seventeen years ago when he was 16 years old, Preston was in an automobile accident from which he emerged physically disabled and confined to a wheelchair.

"Learning to adjust to my new disability and being a disabled black person led to a lot of unusual problems," he observes mildly.

"I learned a lot about myself all at once. Previously, I had negative feelings and ideas about disabled people because I didn't see them in the community, working at jobs, being independent, happy or coping.

"Then, all of a sudden, I saw myself that way—I had no role models at all.

"The loss of identity following disability and then regaining it, was the hardest part."

Preston, a striking, elegantly dressed man, talks slowly and thoughtfully about his experience at the Help Center, where he counsels faculty and staff on personal and work-related problems.

When he began at the Help Center last September, he was apprehensive about his ability to cope with crisis intervention on a steady basis.

But he feels he has adjusted well.

"I think this stems from my experience as a disabled person. When I first became disabled, I was not sure how or even *if* I would be able to accomplish things that previously had been simple, like crossing the street.

"Everything was suddenly a challenge, often an obstacle to be overcome.

"Part of my adjustment meant becoming less frightened of experiencing things, since I had to throw myself into uncertain situations if I wanted to achieve anything.

"We all have to come to terms with our own limitations, not just those of us who are physically disabled. I see many people who are continually disappointed by the expectations they hold for themselves. Resolving this issue through a gradual growth of self-confidence may help immensely.

"For instance, when I counsel disabled people, one of the first things we must deal with is their self image and their motivation to take risks. Every time they successfully cope, the added strength they achieve is amazing.

"This is true for able-bodied people as well, and it's very rewarding to watch the strong person emerging.

-more-

"Being able to help 'normal' people has, in turn, enabled me to grow and realize my own abilities."

Preston is extremely enthusiastic about the success the Help Center has achieved at Stanford.

"When you have problems with work, it can affect your entire lifestyle—where you live, how well you live, where your kids go to school, what you do in your leisure time.

"It's a real plus for a large institution to acknowledge this with a service like the Help Center and to try to deal with the whole person, not just the 'employee'."

At the Rehabilitation Engineering Center at Children's Hospital at Stanford, Preston works with disabled children and their families, evaluating control devices from a psychosocial standpoint, to make sure they actually work effectively for the individual.

He is also devising and assessing more effective methods for disseminating information on available controls to those who could benefit.

When he turns to the subject of social prejudices against the disabled, Preston recounts some disturbing experiences, without bitterness, but revealing a sure determination to achieve his goals.

For example, he recalls an incident from last summer, when he planned to take the state exam for licensing clinical social workers.

"I drove all the way to Sacramento only to discover the exam was being held in a building with a huge staircase and no other way in, and no one to help. I had to drive back home, without even getting inside the building.

"I wrote a letter to state officials, requesting my test fee back, my gasoline costs, and an accessible location in which to take the exam.

"I received no response for weeks, and with much frustration, contacted a local television station, where a reporter decided to look into the issue.

"Just then, the state called and gave me less than a week's notice that I should take the exam in San Francisco on the following Saturday. I had no study materials with me—they were in storage since I had just moved—but I had no choice but to go take the exam, prepared or not."

Preston feels his personal disappointment resulted in a more important victory—the state will not schedule the exam in an inaccessible location again, he says.

But Preston is clearly a man who most enjoys dealing with other people on a personal level, and does so in an open and easygoing manner.

Often, when engaged, he begins to speak rapidly, presenting an experience or a remark of extreme insight that encapsulates one of life's truths simply, movingly, and in a heartfelt way.

"About one year ago, I had an experience that was rare and wonderful," he recalls.

"There was a high school counselor who helped me tremendously shortly after my accident. When I felt I could never return to school, she convinced me that I could. When I graduated, she helped me find a college that would accomodate disabled people, a difficult task back in 1967. (Preston attended the University of Illinois.)

"Last year, on the occasion of her retirement, I was invited to go back to the midwest to give a speech in her honor, one of the most wonderful experiences I have had.

"It was almost as though, in some small way, I could publicly acknowledge and in part pay her back, for all that she had done for me. It is extremely rare for one to have that kind of opportunity."

You can't help feeling, once you've talked with John Preston, that he is a person to whom others must feel a similar debt.

Multiple sclerosis—the causes, worldwide distribution and general nature of the disease—will be discussed on March 20 by Dr. John F. Kurtzke, the 1980 George A. Zimmermann Lecturer at Stanford University School of Medicine.

The lecture, entitled "Multiple Sclerosis: An Epidemiological Attack," will begin at 5 p.m. in room M106 at the Medical Center. It is open to the medical community and to the public.

Kurtzke, a noted epidemiologist, is professor of neurology and community medicine at Georgetown University School of Medicine, and chief of the neurology service at the Veterans Administration Medical Center in Washington, D.C..

He will be the fourth annual Zimmermann visiting professor in the department of neurology.

Kurtzke received his M.D. from Cornell University Medical College in 1952, and has been a member of the Georgetown University faculty since 1963.

The Zimmermann Lectureship was established in 1977 in the neurology department, as part of a $500,000 gift of the late George A. Zimmermann for multiple sclerosis research and treatment at Stanford.

A prominent San Francisco businessman, Zimmermann died in 1974. He bequeathed virtually all of his estate to various charities and for medical research.

Dr. Jerry R. Mitchell, of the Institute for Lipid Research, Baylor College of Medicine, in Houston, Texas, will deliver the William N. Creasy Memorial Lecture at Stanford University School of Medicine on Thursday, March 20.

The lecture, on the ability of the liver to eliminate toxic substances, is open to the public, and will begin at 4:15 p.m. at the Pharmacology Department Library, Room R-358, in the Medical School.

Mitchell is professor of internal medicine and chemical toxicology and chief of the section on hypertension-clinical pharmacology at Baylor. His research interests include clinical pharmacology and toxicology, cardiovascular pharmacology, drug metabolism, and biochemical and chemical reaction methods.

In addition to the lecture, Mitchell will spend the week of March 16 at Stanford teaching medical students, housestaff and postdoctoral fellows, under a William N. Creasy Visiting Professorship in Clinical Pharmacology.

The Professorship is one of 10 awarded this year by the Burroughs Wellcome Fund in honor of the late William N. Creasy, former president and chairman of the Fund.

The Burroughs Wellcome Fund is a nonprofit, private foundation located in Research Triangle Park, North Carolina, and supported by the pharmaceutical firm, Burroughs Wellcome Co.

STANFORD—

Recent proposals by several experts calling for separate standards in screening black and white children for anemia are based on inadequate evidence and it would be a mistake if they were adopted, according to a Stanford University professor.

Some recent studies have concluded that there is a genetic basis for the observed difference in average red blood cell counts (hematocrits) between black and white children.

But these studies are based on inadequate evidence and do not take into account economic factors that are linked with environmental and nutritional causes of anemia, according to Dr. Diana Dutton, assistant professor of family, community and preventive medicine.

"If lower standards for blacks were adopted, some black children who are now eligible for food supplementation and medical care would be ineligible simply because illness had been redefined," Dutton said.

The observed difference of two to three percent in average hematocrit levels of black and white children has been attributed to a combination of environmental, nutritional and genetic factors, Dutton said in an article published recently in the *Journal of the National Medical Association.*

But several researchers have proposed that the difference is genetic. The key issue, according to Dutton, is whether socioeconomic disparities between the racial groups have been adequately taken into account.

Poor nutrition and other conditions of poverty are known to cause anemia, she noted.

One of the proponents of separate standards is Dr. George Owen of the School of Public Health at the University of Michigan in Ann Arbor.

Some proponents of separate standards in anemia screening argue that advantages would include "a reduction in the proportion of black infants and children considered to be anemic and at nutritional risk and who therefore necessarily require special food supplementation or medical intervention."

This might mean that treatment currently going to black children would be given instead to white and other children thought to be in greater need, Dutton pointed out.

- more -

Proponents of separate standards also argue that there would be a reduction in the "considerable financial burden placed on either the government or the individual," and fewer black children would suffer the "psychologic stress associated with having a 'disease'."

"These are certainly advantages, if some black children are presently being inappropriately defined as anemic," Dutton observed.

"Yet the evidence for this is uncertain, and the risks of untreated anemia are serious, including abnormal mental function and development, behavioral problems, physical growth retardation, and susceptibility to infection. At present, many black children, even those with the most serious hemoglobin deficiencies, go without needed nutritional or medical therapy," she said.

Dutton contends that on the basis of current evidence, economic factors cannot be eliminated as a possible cause of the reported racial differences in hematocrits.

"To control for economic factors, previous studies have compared specified economic subgroups, but the subgroups have been fairly broad and are likely to contain substantial economic disparities between the races," she said.

"It is therefore impossible to determine from existing data how much of the racial differential reported is genetic and how much is poverty-related."

From a study of children in Washington, D.C., Dutton found that some of the specific risk factors for anemia associated with poverty include larger family sizes, less educated household heads, more crowded housing conditions, less frequent children's health checkups, and less access to private health care sources.

"The role of genetic factors could best be examined in a prospective comparison of racial groups carefully matched on economic, cultural and dietary factors, with close dietary and medical supervision," she suggested.

"Without this kind of evidence, policy recommendations are premature."

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos 415: 497-6911

STANFORD—

A Stanford-Palo Alto physicians' liaison committee has tentatively agreed on a plan to provide future limited access of community physicians to Stanford University Hospital's special facilities and laboratories.

The committee has been meeting for more than a year to resolve differences between the community physicians and the University.

A central issue has been the question of access of community doctors to hospital-based services now restricted to full-time faculty. These services include anesthesia, neurology, pathology, and the radiology service with its diagnostic, nuclear medicine and radiotherapy divisions, as well as all other specialized laboratories, including cardiology.

Under the proposed plan community physicians would have controlled access to the hospital-based services excluding pathology, but including electrocardiography.

As current community doctors holding privileges in the designated services leave or retire, they will be replaced by community doctors who hold clinical faculty appointments in the Medical School.

"The replacing doctor would acquire privileges identical to those of the departing doctor," according to the plan. "Replacements would be made either on a head count or full-time equivalent basis, as specified in advance for each affected service."

The liaison committee is co-chaired by Dr. Walter Arons, a community physician, and Dr. Lawrence G. Crowley, acting vice president for medical affairs and dean of the School of Medicine.

Arons and Crowley said a progress report containing points on which there is substantial agreement and others that require further work was mailed to the medical staff of the Hospital Tuesday, March 11.

One key area remaining unresolved is final agreement on the formula which would be used as a basis for replacement of community physicians in the hospital-based services.

Eventually any committee recommendations will be submitted to the Board of Hospital Directors for consideration.

The report said that both Stanford and the community physicians on the committee agree that Stanford University Hospital is a university hospital with a unique historical association to Palo Alto and the community physicians. They also agree that the Hospital has a dual mission of furnishing quality medical care to the community and of serving to further the educational and research missions of the School of Medicine.

This educational mission is carried out by the full-time, part-time, and voluntary clinical faculty, the latter composed primarily of community physicians.

- more -

2-2-2

The report stated:

"We have come to recognize that the criteria and procedures that govern the appointment of physicians to the clinical faculty are central to all other questions of access to and privileges within the Hospital, as well as to the quality of the teaching program."

Accordingly, said the report, a committee appointed recently by the acting vice president for medical affairs and dean will formulate criteria and procedures for appointment of replacement physicians to the clinical faculty. The committee is composed of regular and clinical faculty.

In addition, the tentative agreement includes that:

- Replacement physicians would be expected to take active part in teaching, including the appropriate voluntary participation of their patients in educational and clinical research activities.
- A small number of courtesy staff appointments in several hospital-based services would continue to be filled as specified by the contract between the University and the City of Palo Alto.
- Service Access Committees would be formed to review applications for staff privileges in the hospital-based services. The committees would consist of regular faculty, clinical faculty and the chief of each service. The procedure would include a process of evaluating appeals.

The committee agreed that how doctors are compensated for their work should not be a criterion for appointment in the hospital-based services.

"The University members of the committee strongly prefer that new appointees to the hospital-based services should become part-time paid faculty members," the report said.

"Although the community members do not accept this as a necessary condition for replacement, the entire committee agrees that such arrangements, if reached by mutual agreement, are not objectionable in principle.

"Each service should be encouraged to work toward the alternative that best fits its needs and mission."

Tentative agreement also includes the need for each clinical service of the Hospital to form steering committees of full-time and community doctors to review topics of mutual concern.

"We endorse the intention of the School to appoint voluntary clinical faculty to relevant academic departments and School-wide committees, and to explore other appropriate ways of better integrating voluntary clinical faculty into the academic life of the Medical School," the report said.

Other areas remaining to be resolved is the request of specific physicians for certain privileges in hospital-based services, and the possible expansion of the number of community doctors in services in which they now have privileges, or in services where no such staff privileges exist.

Community physicians on the committee are Walter Arons, Walter Bortz, David P. Cooney, Robert W. Jamplis, George P. Janetos and Burt McDowell.

Stanford members are Malcolm Bagshaw, John Collins, Lawrence G. Crowley, Conrad F. Gullixson, Philip G. Larson, Peter Levin, Kenneth L. Melmon, Mrs. Linda Meier, Robert Rosenzweig and James Silverman.

Editors: This is the first in a two part series on the "science of birth," new techniques which are revolutionizing the diagnosis and treatment of illness in the fetus before delivery. Photos available if not included with story.

THE SCIENCE OF BIRTH—PART I

STANFORD—

Medicine is moving beyond the boundaries of birth. New genetic counseling techniques, the use of ultrasound, and special drug treatments have enabled doctors to diagnose and treat illnesses in the fetus before delivery.

The rationale for this new "science of birth" (properly called perinatal medicine) is to decrease the risks of illness or death to both mother and fetus during pregnancy.

"The risks of dying once one is born are never as great as during birth—until one is 85 years old," says Dr. W. LeRoy Heinrichs, chairman of the department of gynecology and obstetrics at Stanford University School of Medicine.

These risks can result from diseases carried by the mother, such as diabetes or high blood pressure, genetic defects carried by the fetus, and even social and economic factors, especially poor nutrition and health care during pregnancy.

"The focus of modern obstetrics (at Stanford as elsewhere)," Heinrichs says, "is to determine health, or disease, while the fetus is still in the womb, and treat it accordingly before it is jettisoned into life, independent from the mother."

Currently, there are several methods of determining ill health in the developing fetus. If there is the possibility of genetic abnormalities, based on family history or age of the mother, an amniocentesis can be performed.

This procedure, done at about the 15th week of pregnancy, involves removal of a sample of the amniotic fluid which surrounds the fetus, by a needle inserted through the mother's abdomen. Cells shed by the fetus into the fluid are grown in culture for two to three weeks, and examined in the laboratory.

Over 50 chromosomal and inherited biochemical abnormalities can be detected in this way. The most common test performed at Stanford's Genetic Counseling Clinic is chromosomal analysis of fetal cells for Down's syndrome (mongolism), a genetic disease characterized by 47 instead of 46 chromosomes, and serious mental retardation.

The frequency of this condition increases with the age of the woman at conception, and amniocentesis is encouraged especially for women over 35 who are pregnant for the first time.

-more-

Early screening allows couples the choice of continuing or terminating the pregnancy, if a genetic defect is found. "We meet with every couple referred to Stanford to discuss the risks for a baby with Down's syndrome or other genetic disorders," says Dr. Howard Cann, director of the Genetic Counseling Clinic. "We provide as much information as possible, but the decision, to terminate or continue the pregnancy, rests with the couple."

Recently, researchers in the departments of genetics and pediatrics reported a new technique which may improve prenatal screening and provide an alternative to amniocentesis.

Using a device developed by Dr. Leonard Herzenberg, professor of genetics, the researchers have been able to detect the presence of fetal cells in the mother's blood stream as early as 15 weeks into pregnancy.

The device, called a fluorescence activated cell sorter, separates fetal cells from the maternal blood on the basis of a fluorescent label they absorb in the study.

Cann, who conducted the research with Herzenberg and their colleagues, cautions that the technique is "strictly experimental. We still are not sure we can grow cells in culture once we separate them," he says. "Practical application is at least five years off."

The incidence of chromosomal abnormalities picked up by screening at Stanford is between one and two percent; out of 358 recent amniocentesis procedures performed in a one year period, five abnormal fetuses were found.

Nevertheless, Cann says, thousands of birth defects in children throughout the U.S. are not detected until birth. Many women who need amniocentesis don't have it done, and even if every woman with the appropriate indication was screened, "there are many birth defects which are not associated with any known biochemical or chromosomal abnormality, and for which we cannot test," he says.

Tracking the fetus with sonar

Alternative methods of screening, notably ultrasound scanning, may improve that record. Originally developed by the armed forces as a means of detecting sea-going vessels, sonar, or ultrasound, has added another dimension to prenatal monitoring.

The ultrasound scanner works by bouncing a beam of sound waves off internal structures, such as the fetus and uterus, and constructing a picture of the echoes.

"Obstetricians would like to know three things about the fetus at each prenatal visit," says Dr. Desmond McCallum, assistant professor of gynecology and obstetrics. "How old is the baby? Is it the appropriate size for its gestational age? And how well is it?"

According to McCallum, ultrasound scanning is the most accurate way to determine fetal age early in pregnancy. As early as seven weeks after conception, the scanner can pick up a heart beat. Two weeks later, fetal movements can be seen.

-more-

Until about 14 weeks, fetal size can be estimated by measuring the length of the fetus from the crown of its head to its rump. After 14 weeks, measurements of the cranial diameter are used to estimate age. Serial measurements of head and body size can monitor growth.

In addition, ultrasound can pick up abnormalities in the placenta, and in the quality of amniotic fluid, which may indicate problems with the pregnancy. According to Dr. Barbara Carroll, assistant professor of radiology, birth defects of the central nervous system, such as spinal bifida, also can be detected with ultrasound scans.

With Drs. Dieter Enzmann and David London, Carroll is using ultrasound to detect intracranial bleeding in premature infants just after birth. This condition strikes an estimated 40 to 70 percent of these tiny babies, and can lead to brain damage.

One of the most important uses of ultrasound is in determining the presence of twins, McCallum says. The death rate among twins is at least five times that of single fetuses, he says. If twins are detected early, however, "we can prescribe less extensive physical exercise and a special iron-rich diet, and, if indicated, monitor fetal well-being throughout pregnancy."

Another form of ultrasound, Doppler, may prove useful in determining overall fetal well-being. The technique bounces sound waves of a certain frequency off red blood cells moving through blood vessels, and measures the change in frequency of the echoes. Currently, this technique, as well as the electrocardiogram, is used to measure variations in the rate of the fetal heart beat. A healthy fetus is expected to have a wide variability in its heart rate, while one which is suffering from a chronic oxygen shortage would have little variability.

McCallum is using Doppler ultrasound to study the characteristics of blood flow velocity in the umbilical vessels, as another measure of fetal well-being.

Fetal therapy

Perhaps the most dramatic advance in maternal-fetal medicine is "fetal therapy," treating the fetus before birth. Blood transfusions for fetuses which suffer from anemia have been performed for several years. But recently, physicians have been able to treat other conditions, including complications of premature delivery, in the womb.

"Prematurity is the leading cause of death among newborn infants in the world," says Dr. Kent Ueland, professor of gynecology and obstetrics. A main complication of prematurity is respiratory distress syndrome, a condition in which babies cannot breathe normally.

These babies are born with immature lungs; some die, and others must be helped to breathe in the intensive care unit for days or weeks, until their lungs catch up to the rest of their bodies.

To minimize the risks of prematurity, doctors at Stanford interrupt premature labor with drugs, such as ritodrine, and give other drugs, notably steroids, to stimulate lung maturity, before delivery occurs. The babies are born, still premature, but with robust lungs.

-more-

Heinrichs recently reported that treatment of the mother with steroids for one to two days before premature delivery significantly decreases the incidence and severity of respiratory distress among their infants. The research was conducted with medical student Porter Storey, now a research fellow at Vanderbilt University.

Despite advances in screening and treating illnesses in the fetus, high rates of disease and death among mothers and infants persist, particularly in the lower socioecomonic areas, and among certain age and racial groups.

The California Department of Health Services recently reported that babies born to women under 15 are two to four times more likely to have neurological abnormalities than those born to women aged 20 to 25. Yet 45 percent of these mothers fail to receive prenatal care in the first trimester of pregnancy.

In addition, the infant death rate may vary by a factor of six between two different socioeconomic groups in adjoining communities, depending on the availability of health care.

Clearly, the advances of technology are not reaching these women. What is needed is a comprehensive program of perinatal education. Such a program, called the Santa Clara Perinatal Project, was established in 1979 at the Santa Clara Valley Medical Center in San Jose, under a $219,000 grant by the State of California.

The goals of the Project are to provide intensive education for high risk mothers, outreach programs for community health care providers, and a regional perinatal center for critically ill mothers and babies.

According to project director Dr. Paul Hensleigh, about 200 women selected at random from the south and central regions of San Jose will be evaluated carefully during the course of their pregnancies this year. All the women are at high risk for complications, whether from medical diseases or socioeconomic problems.

But physical disorders are often not the only problems facing high risk women. "For many women, pregnancy is a life crisis, which compounds problems they may be having at home or at work," says health educator Paula Dase.

"And if the crisis is further complicated by a high risk medical condition such as diabetes, it can make for a potentially volatile situation," she says.

"The Perinatal Project is attempting to meet those needs in pregnancy through education, counseling, and support in a more humanistic approach to health care."

Project team members help patients participate in their own medical care. For example, nurse practitioner Nancy Adams teaches diabetic patients to monitor their blood sugar levels at home. "We've found that when the blood sugars are kept in the normal range during pregnancy, the outcome for infants of diabetic mothers improves dramatically," Hensleigh says.

Editors: This is the second in a two part series on the "science of birth." This article covers advances in treating infertility.

THE SCIENCE OF BIRTH—PART II

STANFORD—

Infertility, the inability to have children, now can be treated successfully in a majority of cases, thanks to advances in medical and surgical treatments.

These treatments include the manipulation of natural hormones responsible for ovulation (production of eggs), microsurgery to repair damaged or diseased reproductive organs in both males and females, as well as the sophisticated technique for fertilizing the egg outside the womb which gained world wide attention with the birth of the first "test tube baby" in 1978.

An estimated one couple in every six have trouble conceiving. In the U.S., 10 million people at any one time are unable to have children.

According to Dr. Emmet Lamb, director of the Infertility Clinic at Stanford University School of Medicine, infertility may result from a variety of reasons, including low sperm count, irregular or absent ovulation, obstruction of the fallopian tubes, which carry the eggs from the ovaries to the uterus, or damage to the uterus' inner lining, the endometrium.

Because many factors may be involved in infertility, diagnosis of the problem can resemble a detective's search for clues. At Stanford, for example, doctors first examine the medical histories of both partners for past diseases or injuries which could impede conception.

Irregular cycles can be detected by having the woman keep temperature charts (a shift to a higher temperature during a cycle indicates ovulation), and problems with sperm in the male can be uncovered in a simple analysis of semen.

Other, more sophisticated tools are used to diagnose problems in the woman's reproductive organs, including techniques for taking X-ray films of or looking directly into the uterus.

In vitro fertilization, fertilization outside the womb, is not performed at Stanford, and besides, most problems can be corrected with more conventional techniques, says Lamb.

For example, problems with ovulation can be treated by giving drugs to correct an imbalance among the complex interaction of hormones which regulate egg production. At least 50 percent of women treated for ovulation problems at Stanford are later able to conceive, Lamb says.

- more -

Microsurgery is employed to treat infertility which results from blocked fallopian tubes. Surgeons may use electrocautery with a fine needle to remove patches of scar tissue which obstruct the tubes.

If the ends of the tubes are closed by disease, they can be opened surgically.

Even previous sterilization procedures can be reversed by microsurgery. For example, pregnancy is achieved in approximately 70 percent of women whose tubes had previously been cut and "tied," simply by reopening the tubes and sewing the ends back together, says Dr. David Adamson, fellow in reproductive endocrinology and infertility at Stanford.

However, if the tubes were closed by cauterization, or burning, the success rate in reversing sterilization drops markedly, he says.

Similarly, 40 to 50 percent of couples in whom the man has had a vasectomy are able to conceive following a reversal operation, according to Dr. Robert Kessler, assistant professor of surgery.

Kessler says that both men and women increasingly are requesting reversal surgery. Between 50 and 75 reversals of vasectomies are performed at Stanford each year, and similar numbers of women come to the Infertility Clinic requesting reversal of tubal sterilization.

Most commonly, he says, people seek the operations because they have remarried and desire children by their new spouses.

Infertility is usually thought of as a female problem, yet in half the cases it is caused by a male factor, says Kessler.

Male infertility can result from disease, hormone problems, birth defects, and from varicose veins of the testes.

Varicose veins lead to a pooling of blood and an increase in temperature, thereby damaging the cells which produce sperm. The condition is treated surgically by removing the varicose veins, and allowing other, normal veins to take up the circulation of blood.

In addition to surgery, drugs such as caffeine can be given to improve mobility of sluggish sperm, or other agents, to decrease the viscosity of the semen.

About half the couples in which a male problem is identified will conceive after treatment. In the remaining 50 percent, artificial insemination or adoption may be recommended. Artificial insemination is achieved by injection of healthy sperm from a donor into the uterus during ovulation.

STANFORD—

Patients at Stanford University Hospital now have their own television channel.

Beginning the first week in March, Channel 3 on the Hospital's TV sets will broadcast four hours of health education programming during the afternoons, Sundays through Thursdays.

The channel is free, and patients do not have to rent the television sets to turn it on.

"Channel 3 will be an important addition to the Hospital's patient education and orientation efforts," said Gary Mecklenburg, Hospital administrator.

"We encourage doctors and nurses to use the channel to supplement their own patient education programs."

Currently, patient education is provided daily to both inpatients and outpatients at the Hospital by doctors, nurses and other health professionals.

Programming of the new channel was developed by the Hospital's Allied Health Council, under the direction of council member Karen Richards, R.N.

Technical assistance is being provided by the Medical Center Instructional Media Department.

Programs include "what to expect from surgery," sports medicine, over-the-counter drugs, "how to stop smoking," and an examination of what makes up hospital bills.

Music and inspirational features also are broadcast.

Television guides detailing programs and schedules will be provided in patient rooms. In addition, patients will be asked to evaluate the new channel and suggest changes in the programs during a six month pilot period.

According to a statement by the Allied Health Council, the goal of the new channel, as of any patient education, "is to help individual patients acquire new knowledge, attitudes, and behavior that will promote their ability to care for themselves more adequately.

"Patients should have an opportunity to know the status of their health, the nature of their problems, what community health resources are available to them and their families, and what they can do to prevent future recurrence of illness.

"Patient education can be a positive force in the recovery from illness and in the alleviation of fear," reads the statement.

Editors: Photos of talking wheelchair available if not included with story

STANFORD—

Researchers at Children's Hospital at Stanford have developed a "talking wheelchair" which gives speech to people unable to communicate because of cerebral palsy, strokes, and other disabilities.

The device, called a "versatile, portable speech prosthesis," consists of a computerized word processor combined with a speech synthesizer.

Users construct sentences on a video screen attached to the wheelchair using a keyboard, joystick, or even a single switch, and then direct the microprocessor to "speak" from a box containing the synthesizer.

The system is powered by a standard 24 volt wheelchair battery.

So far, six individuals with various degrees of speech disability have used the device on a trial basis with relative success.

One woman, who is unable to speak because of a movement disorder, recently used the device to "read" stories to her five-year-old son for the first time, said Carol A. Simpson, Ph.D., a psycholinguist who designed the language generation program.

"Needless to say, she was very excited," Simpson added.

Simpson and her colleagues at Psycho-Linguistic Research Associates in Menlo Park, California, developed the device with Maurice LeBlanc, chief of rehabilitation engineering at Children's Hospital, and Charles D. Lingel, an electronic engineer.

The project was supported by a grant from the National Aeronautics and Space Administration (NASA) Ames Research Center in Mountain View, California.

The device was demonstrated to speech therapists, physicians and educators March 1, at the Southern California Communication Aids Fair in Los Angeles. According to Simpson, several companies have expressed interest in marketing the device.

An estimated one and a half million people in the U.S. cannot speak understandably and can potentially benefit from communication aids such as the talking wheelchair, Simpson said.

The talking wheelchair project evolved from NASA-Ames research on synthesized speech displays for use in the cockpits of commercial aircraft.

Funding and technical assistance for the project was coordinated by the Stanford University Biomedical Applications Team, a program established by NASA in 1966 to transfer aerospace technology to the solution of biomedical problems.

- more -

The goal of the project, said LeBlanc, was to design a "smart" speech prosthesis which allowed people to say anything they wanted in as short a time as possible, no matter how limited their physical dexterity.

The computer program consists of several commands controlling selection of phrases, words, and individual letters, which enable users to construct messages on a video screen. Another command activates the "talk" function.

The words are organized into different "pages" in the computer program, such as a question page, a page of useful phrases, and a dictionary of 925 commonly used words.

Depending on the severity of their physical disabilities, users may punch characters into a keyboard, move a joystick, or simply click a switch at appropriate intervals to construct the messages they wish to speak.

In addition, they can store completed sentences in the system indefinitely, for use at a later time.

Thus, they can build up a "library" of spoken messages so that they can go shopping, order a meal at a restaurant, or even read class assignments in school, Simpson said.

Experienced users of the keyboard model can construct sentences as fast as 30 words per minute.

Currently the voice is produced by a Votrax phoneme speech synthesizer, which has a male voice with a slight mechanical ring. The pitch, rate and volume of the speech may be adjusted to suit the user.

Researchers are attempting to make the voice sound more natural by adding components to its wave form, Simpson said, but it will be some time before a female voice is commercially available.

"Unlike the male voice, we don't have sufficient acoustic data on how the female voice is produced," she said.

Editors: Photos of Baylor available if not included with story

STANFORD—

Dr. Denis Baylor, professor of neurobiology at Stanford University School of Medicine, has been awarded the Rank Prize in Opto-electronics for his research on the visual system.

The prize, 21,000 British pounds or about $50,000, was presented to Baylor Tuesday, March 4 at the Royal Society in London. It will be shared with Baylor's colleagues, Drs. Trevor Lamb and King-Wai Yau, research associates at Cambridge University.

The prize recognizes "the development of a new technique for recording the electrical currents generated by single photoreceptors in the vertebrate eye."

Photoreceptors, commonly known as rods and cones, are the cells in the retina which convert light into electrical signals. In the brain, these signals produce the sensation of vision.

In 1977, Baylor, and Lamb and Yau, then postdoctoral fellows in his laboratory, developed a technique for sucking a single rod cell into a tiny electrode, and measuring the change in electrical current flowing across its surface when the cell is exposed to light.

The technique may help scientists understand how the visual system works.

Baylor, 40, is internationally known for his pioneering work in the neurobiology of light reception by the vertebrate eye.

He is a 1961 graduate of Knox College in Galesburg, Illinois, and received his M.D. from Yale University School of Medicine in 1965.

He served as research associate at the National Institute of Neurological Diseases and Stroke and at Cambridge University, and was associate professor of physiology at University of Colorado Medical School before coming to Stanford in 1974.

An editor of the *Journal of Physiology,* Baylor has published over 50 articles in scientific journals. He received the Sinsheimer Foundation Award for Medical Research in 1975.

The Rank Prize in Opto-electronics is awarded by the Trustees of the Rank Prize Funds, and is one of two prizes established in 1972 by the late Lord Rank. The other award is given in the field of animal and human nutrition and crop husbandry.

The awards are made to individuals for notable achievements and also to encourage research and sponsor scientific symposia.

In addition to Baylor, this year's Rank Prize in Opto-electronics was awarded to five British researchers for their work on the liquid crystal.

STANFORD—

Dr. William Fowkes, head of the division of family medicine at Stanford University School of Medicine, has been appointed regional director of the Area Health Education Center (AHEC) for San Mateo and Santa Clara Counties.

Virginia Fowkes, who directs the Primary Care Associate Program at Stanford, is associate regional director.

AHEC is a national program supported by the federal government for the purpose of disseminating medical center resources and knowledge to underserved communities through health manpower education projects.

Stanford is participating in the California AHEC, which is directed by Dr. Malcolm Watts, of the University of California at San Francisco.

The regional AHEC office will open at 703 Welch Rd. in July, and an advisory committee representing the Medical School, San Jose State School of Nursing, and the allied health training programs at Foothill College has been appointed to plan and review AHEC projects.

The committee will work with the local Health Systems Agencies to plan projects such as continuing education for physicians.

Dr. Fowkes said it is hoped that these projects will become self-sufficient through state or local funding, and will continue even after the AHEC program has been completed.

—30—

STANFORD—

A new affiliation agreement to train physicians in family medicine has been made between Stanford University School of Medicine and San Jose Health Center.

The agreement was announced recently by Medical School Acting Dean Lawrence G. Crowley and Health Center President John C. Aird.

It coordinates the resources of the Health Center's already-existing family practice residency program and Stanford's Department of Family, Community and Preventive Medicine.

Stanford and the Health Center also cooperate in the training of child psychiatry residents, physical therapy students, and physicians assistants.

"This new agreement broadens the clinical experiences of Stanford's residents, by exposing them to a different patient population than they would encounter in the mid-Peninsula," said Dr. William Fowkes, who directs both the residency program and the division of family medicine at the Medical School.

"At the same time, it enables the residents at the Health Center to participate in rotations at Stanford, use the library and other facilities, and engage in research activities.

"Both groups can only benefit from such cooperation," he added.

According to the agreement, San Jose Health Center will provide at least one clerkship and regular elective rotations for Stanford medical students and residents in the family practice program.

In return, the University will allow family practice residents to participate in rotations at Stanford Hospital, and to use the medical library and related facilities.

The director and faculty members of the family practice residency program will be appointed by the Health Center, and if acceptable, will be appointed to the clinical faculty of the Medical School. Stanford faculty will assist in training family practice residents.

Family practice faculty members will have access to the Medical School's divisions of biostatistics and health services research for consultation and research purposes.

The agreement is effective for one year beginning March 1, 1980, and will be extended thereafter on a year-to-year basis.

An affiliation liaison committee representing the administrations of both institutions will provide on-going review and approval of the program.

STANFORD—

The second spring Progress in Medicine lecture, part of Stanford University Medical Center's twentieth anniversary celebration, will be held Tuesday, May 6 at 7:30 p.m. in Fairchild Auditorium.

Drs. George Harell and Richard Popp will discuss new ways to diagnose disease, and patient care in the 1980's.

The lecture is free and open to the public.

Harell is associate professor of radiology in the division of diagnostic radiology. An expert on computed tomography (CT), he will explain how CT scanning differs from conventional x rays and will discuss current uses and future applications of whole body CT.

Harell received his M.D. in 1963 from Columbia University College of Physicians and Surgeons. He joined the staff at Stanford Medical School in 1972.

Popp, associate professor of medicine in the division of cardiology, is a specialist in the field of echocardiography, the use of ultrasound in diagnosis of heart disease. He will discuss the technique's many applications in cardiac and cardiovascular medicine.

Popp received his B.A. from Johns Hopkins University in 1960, and his M.D. from the Johns Hopkins University School of Medicine in 1964. He joined the staff at Stanford Medical School in 1971.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine, the Stanford University Hospital, and members of the Medical Center Council.

The fifteenth annual John Kent Lewis Memorial Lecture will be presented by internationally known cardiologist Dr. Desmond Julian, on May 12 at the Medical School.

The lecture, entitled "Trials and Tribulations in Ischemic Heart Disease," will begin at 4:30 p.m. in Fairchild Auditorium. Physicians and other health professionals in the community are invited to attend.

Julian, professor of cardiology from the University of Newcastle Upon Tyne in England, is also medical director of the Regional Cardiac Centre at Newcastle, the cardiac research and clinical headquarters for northern England.

He originally developed the idea of coronary care, and established one of the first coronary care units in Edinburgh, Scotland.

He has made important contributions to the field of cardiac arrhythmias in patients who have suffered heart attacks, and he is a pioneer in the use of drug treatment in patients following acute heart attack.

The John Kent Lewis Lecture, first presented in 1964, honors the memory of Dr. John Kent Lewis, who received his undergraduate and medical degrees from Stanford in 1918 and 1922. Former chief of the Stanford Medical Service at San Francisco General Hospital, Lewis was a noted pioneer in heart research. He died in 1961.

A one-day workshop for health professionals, on effective weight control counseling will be held at the Medical Center on May 30.

Co-sponsored by the Stanford Counseling Institute and Stanford Hospital's Nursing Educational Services, the workshop will present the latest research results and practical treatment strategies for nurses, dieticians, counselors, and other health professionals who work with patients on weight control.

The workshop will begin at 8:30 a.m. in the Hoover Cottage Lounge at Hoover Pavilion.

Topics to be covered include behavioral analysis methods for identifying negative eating and exercise patterns, self-instruction training and self-motivation, overcoming client resistance to change and practical procedures for conducting weight control groups.

The workshop will be led by two experienced weight control therapists—Gary Dexter, on the staff at the Stanford Counseling Institute, and Joel Killen, a staff member at the Stanford Heart Disease Prevention Program.

An advance registration fee of $40 is required. Early registration is recommended as enrollment is limited.

The workshop can also be presented to staff members at hospitals, professional organizations, and other groups on an individualized "in house" basis.

For more information or to request a registration form, contact Joel Killen or Gary Dexter at the Health Behavior Research Group at 7-3897.

Continuing education credit is available for nurses.

STANFORD—

A team of Stanford University researchers has reported the first long-term survival in monkeys receiving combined heart and lung transplants.

Five in a series of 10 rhesus monkeys that received the transplants are still living up to 312 days after surgery with apparently normal heart and lung function, said Dr. Bruce Reitz, assistant professor of cardiovascular surgery at Stanford University School of Medicine.

If additional animal studies are successful, trials in patients could begin within two years, he said.

Reitz reported on the technique April 28, at the meeting of the American Association for Thoracic Surgery in San Francisco.

He conducted the research with Drs. Nelson Burton, Charles Bieber, Stuart Jamieson, John Pennock, Edward Stinson, and Norman Shumway, of the Medical School's Department of Cardiovascular Surgery.

Reitz said that heart-lung transplants could help patients who have suffered lung damage as a result of heart disease, and those who have bilateral or diffuse lung disease due to a variety of causes.

Transplanting the heart with the lungs is preferable to replacing both diseased lungs alone, Reitz said, because it is surgically easier to remove the heart and lungs as a single package.

In addition, it is almost impossible to biopsy lung tissue as a means of monitoring rejection of the transplanted organ. However, biopsy of heart tissue is done routinely in heart transplant patients, and could provide an indicator of rejection in the combined transplant, he said.

Patients with lung cancer would not be good candidates for heart-lung transplantation, Reitz said, because the disease often occurs in only one lung, and can be treated by surgical removal of the cancerous tissue.

In addition, the immune suppressive drugs used to prevent rejection of transplanted organs may accelerate the spread of cancer to other parts of the body, particularly if some cancer cells remained even after surgery.

The record of lung transplantation in humans to date has been poor, Reitz said. In 38 reported attempts, only two patients have lived longer than three months following surgery, and none survived for longer than 10 months.

Reitz cited three known cases of combined heart-lung transplants in humans performed between 1968 and 1971. All three patients died within 23 days, from pneumonia and failure of the severed windpipe to heal.

-more-

Similar results were obtained previously in animal studies, he said.

The Stanford study differed from previous studies in that a new drug to prevent rejection of the transplanted organs, Cyclosporin-A, was substituted for traditionally-used corticosteroids.

Cyclosporin-A is a fungal derivative which seems to act specifically to block the immune cells responsible for rejecting transplanted tissue without affecting other immune cells that fight bacterial infection, Reitz said.

Infection is a serious problem in the use of corticosteroids, because they indiscriminately destroy all types of immune cells.

Cyclosporin-A also avoids the other complications of corticosteroids, which include delayed wound healing, weight gain, muscle weakness, and progressive bone deterioration, he said.

The Cyclosporin-A used in the study was provided by Sandoz, Ltd., of Basel, Switzerland.

In the study, Reitz and his colleagues performed transplants in 10 monkeys using cardiopulmonary bypass, the technique of circulating blood by machine used during open-heart surgery in humans.

Some of the monkeys received hearts and lungs from unrelated monkeys, and were given Cyclosporin-A to prevent rejection. Others had their organs removed and then reimplanted, and did not receive the drug.

Three of seven monkeys that had received unrelated hearts and lungs survived longer than 140 days after surgery. Two are still living six and seven months after surgery, and are being treated continuously with Cyclosporin-A.

The three animals that had their organs removed and reimplanted are living 60, 199, 312 days after surgery.

None of the monkeys on Cyclosporin-A contracted infections or had problems with healing of their windpipes.

"Success in these experiments is most likely due to the use of Cyclosporin-A," Reitz said.

However, one long-term survivor treated with the drug died after 144 days from a lymphoma, or cancer of the lymphoid tissues, which may have resulted from the immune suppression caused by the drug.

Kidney and heart transplant patients are known to be at higher risk of developing cancer, Reitz said, and in recent clinical trials of Cyclosporin-A in kidney transplant patients conducted at Cambridge University, England, "three recipients developed lymphomas within the first year of treatment."

Despite the risk of cancer, Reitz said the benefits of Cyclosporin-A make it a logical choice for clinical trials of heart and lung transplants.

Dr. Richard D. Mamelok, assistant professor of medicine at Stanford University School of Medicine, has won a faculty development award in clinical pharmacology from the Pharmaceutical Manufacturers Association (PMA) Foundation.

The award provides $30,000 to support Mamelok's research and teaching activities for two years beginning July 1, 1980.

Mamelok, 32, is a graduate of Columbia University, and received his M.D. at Dartmouth Medical School in 1973.

He served as a research fellow in clinical pharmacology at the University of California Medical Center in San Francisco before joining the division of clinical pharmacology at Stanford in 1979.

His research focuses on understanding how certain drugs are transported across kidney cell membranes. The research may lead to improvements in the drug treatment of patients who have kidney failure.

Mamelok also is responsible for teaching medical students and fellows in clinical pharmacology.

A member of the American Association for the Advancement of Science, Mamelok also is a 1979-80 fellow of the Andrew W. Mellon Foundation of New York.

The PMA Foundation faculty development program has aided 51 junior faculty members since it was established in 1967.

It is part of a larger effort by the Foundation to support pharmaceutical and therapeutic advancement through awards to university research and training programs.

STANFORD—

Medical teaching, patient care and research in the decade of the '80's will highlight the spring Progress in Medicine lecture series in April and May at Stanford University Medical Center.

The series is one of several events celebrating the twentieth anniversary of the move of Stanford Medical School from San Francisco to the university campus.

All lectures are open to the public and will be held on Tuesday evenings at 7:30 p.m. in Fairchild Auditorium at the Medical Center.

April 29—*TEACHING: Medical education today*, with Dr. Lawrence G. Crowley, acting vice president and dean of the Medical School, and Dr. John P. Steward, associate dean for student affairs and adjunct professor of medical microbiology.

May 6—*PATIENT CARE: New ways to diagnose disease*, with Dr. George S. Harell, associate professor of radiology, and Dr. Richard L. Popp, associate professor of medicine in the division of cardiology.

May 13—*RESEARCH: The hidden cost of survival of the fittest*, with Dr. Andrei Calin, assistant professor of medicine, and director of the rheumatology section at the Palo Alto Veterans Administration Medical Center, and Dr. Hugh O. McDevitt, professor of medicine in the division of immunology and professor of medical microbiology.

May 20—*RESEARCH: How genes are reproduced and repaired*, with Dr. Errol Friedberg, associate professor of pathology, and Dr. David Korn, professor and chairman of the department of pathology.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine, the Stanford University Hospital, and by members of the Medical Center Council.

STANFORD—

A comprehensive health education program, on ways to reduce the risks of heart disease, will be launched this week by the Stanford Heart Disease Prevention Program in two central California communities.

The program is based on Stanford's "Three Communities Study," which showed that community-based health education relying heavily on the mass media can have a significant impact on helping people to change their lifestyle and improve their health status.

The Medical School and Communications Department at Stanford are coordinating the new education program for three main purposes:

—to demonstrate for the first time that community-wide education programs can reduce heart disease risk, thereby leading to diminished heart attack, stroke and death rates in entire communities,

—to show how health education for young people can prevent the adoption of harmful health practices,

—to show how communities throughout the U.S. can be organized to carry out effective and affordable education programs.

The program kicks off in Salinas and Monterey on Friday, April 18, with the broadcasting of a "heart health test" on Salinas station KSBW-TV (Channel 8) and in Spanish on KRAY Radio (104 FM) beginning at 8 p.m.

Viewers will be able to test their knowledge about many health issues and will learn how changes in food habits, stress, smoking and exercise can reduce their risk of heart attack and stroke.

The health test was produced by Janet Alexander, director of community education for the Heart Disease Prevention Program, in association with Veriation Films of Palo Alto, California.

The program, which runs for five years, also includes newspaper columns, radio and television spots, books on heart disease risks, education for health professionals, new school programs, and classes led by community groups.

-more-

During and following the educational program, randomly selected individuals will be surveyed at yearly intervals for heart disease and stroke risk factors, and data will be collected on the incidence of heart disease and disease-related deaths in Salinas and Monterey as well as three other California cities.

The eight-year study is directed by Dr. John W. Farquhar, professor of medicine at the Medical School and head of the Stanford Heart Disease Prevention Program, and is supported for the first five years by a $6.2 million grant by the National Heart, Lung and Blood Institute.

Dr. Nathan Maccoby, director of the Institute for Communications Research, and Dr. Peter Wood, adjunct professor of medicine at Stanford are co-principal investigators.

The Medical School team includes Drs. Stewart Agras, Byron W. Brown, Jr., Stephen Fortmann, William Haskell, Stephen Hulley, Ralph Paffenbarger, and Barr Taylor.

The communications team includes Alexander, Dr. Douglas Solomon, Prudence Breitrose, Elizabeth Adler, Dr. Edwenna Werner, and Dr. Elizabeth Blackmer.

Although deaths from heart disease and stroke have declined over the last 10 years in the U.S., the disease still kills approximately 170,000 people under age 65 each year.

About 90 percent of these premature heart attacks and strokes can be prevented, says Farquhar.

"We hope to create a climate of opinion that encourages people to think positively about their health, and to provide step-by-step advice that will help them gradually make specific changes in food and lifestyle," he says.

"We will try to help people add to their feeling of well-being and zest for living, while at the same time they reduce their risk of heart disease and stroke."

By enlisting the participation of community groups, Farquhar says he anticipates the educational programs will continue long after Stanford's role in the study has been completed.

STANFORD—

Dr. Stanley Falkow, a noted scientist in the field of recombinant DNA research and infectious diseases, has been named professor and chairman of the Department of Medical Microbiology at the Stanford University School of Medicine.

The appointment is effective September 1, 1980. Falkow is presently a professor of microbiology and medicine at the University of Washington in Seattle.

Falkow is widely recognized for his work on the application of modern concepts and technologies of molecular biology to problems of infectious diseases.

"We are indeed fortunate to attract to Stanford an individual of Dr. Falkow's caliber," said Acting Vice President and Dean Lawrence G. Crowley. "His appointment promises to bring exciting and effective leadership to the academic programs of the department and the School."

The Department of Medical Microbiology has been without a permanent executive since Dr. Sidney Raffel retired in 1976 after 23 years as chairman. At that time Dr. Bruce Stocker, professor of medical microbiology, agreed to serve in an acting capacity until a successor was named.

Falkow's research deals with the way plasmids, circular DNA molecules that reproduce themselves inside bacterial cells, render bacteria resistant to antibiotics, and the way they contribute to the ability of bacteria to produce infectious disease.

He is regarded as an innovative teacher who has trained outstanding young fellows in basic and clinically applied research in the area of human infectious diseases.

The 45-year-old scientist was born in Albany, New York, and was educated in Rhode Island and Maine schools. In 1960 he received the Ph.D. in biology from Brown University.

Before moving to his present post in Seattle, Falkow was a professor of microbiology at Georgetown University Medical School in Washington, D.C..

He is the author of more than 106 published papers in his field, and has served on the editorial boards of *Bacteriology,* and *Infection and Immunity.* He is currently on the board of the *Journal of Infectious Diseases.*

From 1975 to 1978 he served on the advisory committee on recombinant DNA research of the National Institutes of Health, and he is a consultant to the Food and Drug Administration's committee on antibiotics in animal feeds.

In May this year Falkow will present a Kinyoun Lecture at NIH. This lectureship is awarded to eminent scientists who are internationally known in research areas supported by the National Institute of Allergy and Infectious Diseases.

Falkow is married and has two children.

STANFORD—

The United States government is not doing enough to prevent nuclear reactor accidents like the one which occurred last year at Three Mile Island, according to a University of California scientist.

"I'm convinced that a great deal more can be done than has been done to prevent accidents," said Joel Primack, Ph.D., associate professor of physics at the University of California at Santa Cruz, and consultant to the Nuclear Regulatory Commission's special inquiry group on Three Mile Island.

In addition, civil defense and emergency health planners are seriously unprepared for an accident in which large numbers of people are exposed to radiation, he said.

Primack spoke at a symposium on the medicine of acute radiation exposure at Stanford Medical School's Fairchild Auditorium on Saturday, April 12.

The symposium, for doctors and other emergency health professionals, was sponsored by the Stanford Medical Students Association and the Department of Family, Community and Preventive Medicine.

Primack said that the prevailing attitude among builders, operators and regulators of nuclear reactors is that a "melt-down," or overheating of fuel which can lead to release of radioactivity into the environment, is "an incredible accident—they don't have to plan for it."

Yet, the reactor at Three Mile Island was only 30 to 60 minutes from a major meltdown according to the Rogovin Study, the Nuclear Regulatory Commission's report, he said.

Primack criticized the NRC for not investing money in improving reactor safety.

The Commission spends $100 million a year "basically trying to convince us that reactors are safe," he said, yet spends "virtually nothing on improving reactor safety."

For example, it is possible to develop a filter system that could remove 95 percent of the radioactivity released in an accident before it reaches the atmosphere.

However, "the NRC has consistently refused to spend any money developing such a system," he said.

Primack recommended there be some "independent assessment" of reactor operation.

"The NRC is not adequately prepared to play that role. It was days before they understood what was going on at Three Mile Island, and even then they seriously misdiagnosed" the situation, he said.

"The hydrogen bubble scare was largely based on the technological incompetence of the NRC staff."

A second major problem is the inadequacy of civil defense and emergency medical procedures.

Roland Finston, Ph.D., director of Health Physics at Stanford University, said that potentially lethal exposure to radioactivity released in a reactor accident and deposited on the ground can be reduced by three fourths if people in the immediate vicinity (within five to 10 miles of the reactor) are evacuated within six hours.

-more-

Yet, there have been no serious preparations for an evacuation of that magnitude, Primack said. (Approximately 29,000 people live within five miles of the Three Mile Island reactor.)

If an evacuation cannot be undertaken, for example because a snow storm prevents people from moving in and out of an area, "one should be prepared to shut reactors down" as a precautionary measure, Primack said.

One of the most serious health risks from a reactor accident is exposure to radioactive iodine, he said.

The thyroid gland avidly absorbs iodine, and any radioactivity it carries can cause the development of thyroid nodules and even cancer.

Fetal and child thyroid glands are particularly sensitive to radiation because of their smaller size.

Even at a distance of 200 miles from an accident, the thyroid glands of children would receive 500 rems of radiation, enough to cause nodules in 10 to 60 percent of the cases, Primack said.

Fortunately, 90 percent of the absorption of radioactive iodine can be prevented by giving potassium iodide (KI) either before exposure or as quickly thereafter as possible, Primack said.

Potassium iodide is a well understood drug with few side effects, which simply blocks absorption of other radioactive forms of iodine.

Yet, even though the Food and Drug Administration requested in December, 1978 that drug manufacturers submit applications to produce the drug for this purpose, "as far as I know, there still have not been any applications," Primack said.

"Nobody requires potassium iodide to be stockpiled," he added.

Following the accident at Three Mile Island, the Air Force dispatched planes to collect the drug from manufacturers. "One week later, they had 200,000 doses of KI," which were not used and "probably will be dumped."

"That's absurd," Primack said. "Potassium iodide should be stockpiled and distributed widely to people in the vicinity of a nuclear reactor who would not have the chance to get it from some central distribution point."

Finally, "we should be prepared to decontaminate land and water," he said.

Many reactors are located on rivers, placing a substantial fraction of the fresh water of the US in danger of being polluted in the case of a "melt-through," in which the molten fuel melts through the floor of the containment vessel.

"The amount of radioactive strontium, for example, that could be released from the melt, through even one half mile of ground to the local river, would be enough to pollute the entire annual run-off of the Ohio or Missouri Rivers for five years," Primack said.

This could be prevented by drilling wells right around the reactor to suck out the radioactive leakage, he said.

STANFORD—

Stanford University School of Medicine is among 13 private medical schools that will receive grants from the Henry J. Kaiser Family Foundation to help alleviate some of the financial problems facing medical students.

Dr. Robert J. Glaser, president of the Palo Alto-based charitable foundation, said each of the 13 schools will receive an immediate grant of $100,000. A second grant of $50,000, payable, after January 1981, will be provided to those schools that match the second component on a two-to-one basis.

The foundation funding to the 13 schools totals $1.3 million.

"We hope the matching grant will provide the incentive for vigorous fund raising efforts," explained Dr. Glaser, "since foundation resources alone cannot make a significant impact on the indebtedness of students needing aid."

"The challenge grants may enable the schools to increase the awareness of their alumni, other individuals, and corporations about the financial problems facing today's students," he added.

Tuition costs in the 13 schools range from a low of $5,250 to a high of $8,152 per academic year (three quarters), according to the foundation.

(Stanford Medical School's tuition for the same period for new students will be $7,338 in 1980-81. Three-fourths of Stanford medical students borrow funds to meet part of the cost of medical education. Of the graduating M.D. students in 1979, 69 percent had a mean debt of $16,800, according to the Financial Aid Office. Total support of $2.6 million for medical students in 1978-79 at Stanford was composed of about 41 percent loans and 32 percent scholarships. The remainder came from income contributed by students, their spouses and parents.)

Dr. Glaser said the 13 schools are ideal candidates for this effort because eight years ago they formed a consortium whose officers meet regularly to share information on common problems, especially financial assistance for students.

"Because the consortium schools are privately funded and now share a considerable amount of data, they are in a position to test the hypothesis that aggressive fund raising on their part can increase private giving of scholarships," Dr. Glaser said.

"Historically," he noted, "medical alumni contributions have been small relative to their substantial earnings, and medical schools are eager to offer incentives to increase giving by their graduates."

Besides Stanford, medical schools which will receive the grants include Case Western Reserve, University of Chicago, Duke, Harvard, Johns Hopkins, Columbia, University of Pennsylvania, University of Pittsburgh, University of Rochester, Washington University, and Yale.

STANFORD—

Chinese medicine is a balance of two worlds, each in stark contrast to the other.

In the field of infectious diseases, for example, Chinese physicians are gearing up to produce interferon using sophisticated recombinant DNA techniques, while at the same time they are trying to teach people to improve sanitation by keeping their pigs out of their houses.

Improving health care on both fronts is very difficult under the current economic conditions found in this country of 800 million people, according to Dr. Thomas Merigan, professor of medicine and head of the division of infectious diseases at Stanford University School of Medicine.

"There simply are a lot of other things besides improving health care that need to be done," he said.

Merigan recently returned from a month-long tour of several infectious disease research centers and hospitals in the People's Republic of China, as a guest of the Chinese Academy of Medical Sciences.

His observations of the trip were published in a recent issue of the *Journal of Infectious Diseases.*

One example of the problems facing the Chinese in controlling infections is the high rate of polio. According to the World Health Organization, 10,000 cases of paralytic polio were reported by the Chinese last year, two fifths of the world total. In comparison, the U.S., with a population of 240 million, only has about five cases a year.

Another problem is hepatitis. Five to 10 percent of the Chinese people suffer from chronic hepatitis B virus infections, Merigan said, compared with "very much less than one percent" in the U.S.

The high incidence may reflect genetic or cultural differences in susceptibility between the two peoples, as high hepatitis rates occur in other countries, including Japan. However, differences in sanitation and medical techniques could also be to blame, he said.

Not surprisingly, the high rate of hepatitis in China makes it easier for physicians to do long-term studies of patients with the disease. In Canton, researchers at the Chung Shan Medical College have noted an association between hepatitis and liver cell cancer.

Patients with such tumors have an eight times greater likelihood of carrying hepatitis B markers in their blood, as well as giving a history of hepatitis, compared with appropriate controls. In addition, studies of tumor biopsies have uncovered cirrhosis and inflammation characteristic of hepatitis.

At the Institute of Oncology in Peking, Drs. T.F. Sung and Y.H. Chang have found increased levels of alpha-feto protein in patients with liver cell tumors. This protein, which may be produced by the cancer cells, may provide a means of early detection of the disease. Again, Merigan said the great numbers of people with chronic hepatitis make possible this unique large scale study.

-more-

Similarly, the high incidence of nasopharyngeal (nose and throat) cancer in southern China has made it possible for scientists to study the role of Epstein-Barr virus (EBV), which in Africa also has been associated with Burkitt's lymphoma.

Using sophisticated immunological techniques Dr. Y. Zeng and his colleagues at Peking's Institute of Virology have found that as many as 15 percent of individuals over 30 who carry antibodies against certain EBV markers, but who otherwise are without symptoms of malignancy, eventually will develop this cancer.

The Chinese would like to use interferon, the natural anti-viral agent, as well as other anti-virals to try to treat and prevent these cancers, Merigan said. Interferon currently is being tested in the U.S. as a treatment for a variety of cancers.

However, the Chinese program is a long way off, he said, due to a limited supply of the material, which currently is isolated from human white blood cells.

Workers at the Institutes of Genetics and Virology are attempting to develop recombinant DNA techniques for production of interferon by bacteria, a goal also of Western scientists, Merigan said, but as yet have not published many papers on this technology.

Another major thrust of researchers is the study of traditional Chinese medicine, Merigan said. For example, physicians are using modern medical lasers directed at traditional acupuncture sites to treat ailments such as liver disease.

The role of acupuncture, in Western medicine at least, remains unclear. Nevertheless, Chinese researchers have found that acupuncture with the laser seems to be as effective as the technique performed with needles, and the laser beam has the advantage that it cannot be contaminated and thus cannot spread infections, he said.

At the Institute of Virology, Dr. Y.T. How is studying the intriguing finding that an extract of a traditional herbal root can improve the action of interferon in treating recurrent respiratory infections.

This finding, and others like it, may benefit Western medicine, Merigan said, particularly if the active components of the traditional herbs can be purified.

Merigan said that many of the difficulties in improving medical care in China resulted from a period in the late 1960s and early 1970s of "isolationism and anti-intellectualism," during the so-called "Cultural Revolution."

Today, however, "one perceives the re-emergence of a growing group of very intellectually competent, vigorous and enthusiastic individuals who are deeply committed to the development of high quality medical and biologic research," he said.

CITY DESKS: This story is a follow-up to a bulletin transmitted to AP and UPI early this morning.

STANFORD—

An elderly woman patient died and three security people were slightly injured Wednesday night, April 9, when a fire broke out in the patient's room in the Hoover Pavilion of Stanford University Hospital.

Edna Hansen, 76, of 180 Hamilton Ave., died from apparent smoke inhalation and burns suffered in a smoldering fire which began about 10:00 p.m., and which was confined mostly to the upper portion of the mattress of her bed on the third floor of the Hospital annex.

Hospital safety and security supervisor Jerry Murphy and guards Tracy Fry and Jeff Schlesinger were treated in the Emergency Department for smoke inhalation suffered when they tried to put out the fire, and were released early Thursday morning.

According to Palo Alto fire inspector Bob Cleveland, Mrs. Hansen had apparently been smoking in bed.

The body has been taken to Santa Clara Valley Medical Center for autopsy, because it is a coroner's case.

Dr. Bruce Halperin, resident physician on duty, said he attempted to rescue the woman, but the smoke from the burning mattress was so thick he could not enter the room.

He immediately ordered the evacuation of all patients on the ward to the first and second floors, where they will remain until the area is cleaned up, probably early next week.

None of the other patients suffered any complications or came in contact with the smoke, he said.

Despite the fact that some patients were on oxygen therapy and were receiving intravenous medications, Halperin said the entire floor was evacuated within three to four minutes.

"The nursing staff were tremendous," he said. "Their efforts were truly heroic."

Eight units of the Palo Alto Fire Department responded to the alarm, and doused the burning mattress within minutes upon arriving.

Damage to the room was limited to the mattress, curtains, and the wall, which was blackened by the smoke.

The unit on the second floor below the burned room was evacuated briefly by the fire department as a precautionary measure.

According to her physician, Dr. Walter Bortz, Mrs. Hansen was being treated for emphysema and organic brain syndrome, which is associated with mental confusion.

Mrs. Hansen was restrained in bed by a vest worn around the torso. Her arms and legs were not restrained and she could reach the call button which she used frequently during her hospitalization. Hospital officials said it is common nursing practice to use soft restraints in order to prevent certain patients from falling out of bed and injuring themselves.

Dr. Bortz said Mrs. Hansen did not have his permission to smoke. The nursing staff apparently did not know she had cigarettes in her room.

Hospital policy requires that patients who are confined to bed and who wish to smoke must have the permission of the responsible physician, and a responsible adult must be in attendance.

Mrs. Hansen is survived by a niece, Mrs. Dampier, of Los Altos, CA.

Funeral arrangements are pending.

Relax—and help medical research by volunteering for a study on relaxation as a treatment for high blood pressure, being conducted in the department of psychiatry at Stanford University Medical Center.

Each individual in the study will receive three half-hour sessions of relaxation training during the course of one morning, and the last session may be taped for continued use at home, according to Dr. Michael Horne, coordinator for the project.

The relaxation training techniques are presently used in the psychiatry department's stress reduction clinic, he said.

People with high blood pressure who wish to volunteer should call Dr. Horne at (415) 497-6341.

STANFORD—

A $97 million program to correct deficiencies and modernize the Stanford University Hospital and Clinics over the next six years has been proposed by Medical Center administrators.

The plan, still in the preliminary stages, was circulated to the University Board of Trustees, medical committees, and discussed with student leaders Friday, April 4.

The 110-page document, "Facilities Plan and Capital Funding Forecast 1979 to 1985, Stanford University Hospital and Clinics," is part of a long-range planning study launched by Acting Vice President and Dean Lawrence G. Crowley to describe future resources and capital needs of the Medical Center.

Similar planning has been under way at the University to deal with the problem of obsolescence of academic buildings.

The Hospital plan was developed by a team headed by Hospital Executive Director Peter Levin.

Following approval by the Board of Hospital Directors, the proposal will go to the Trustees for action at a future meeting, Levin said.

Still, a plan of this magnitude will require approvals (a certificate of need) from local and state health planners, and city and county agencies. The process is expected to take several months.

Modernization of the Hospital is crucial, the report contends, because clinical and research activities are constrained by "serious functional deficiencies." These compromise the efficiency of the Hospital and its ability to provide high quality care.

A chief problem cited by the report is inadequate space. This results in a lack of compliance with hospital codes designed to safeguard the well-being of patients and staff. Among the deficient units are coronary care, intensive care, pediatrics, radiology, medical records, central sterile supply, cafeteria, and materials storage.

The report adds, "Many other aspects of the Hospital operation are in violation of existing codes and potentially citable."

Two years ago the Joint Commission on Accreditation of Hospitals, the California Medical Association, and the California State Department of Health accredited the Hospital for the normal two years as a result of a major commitment to implement corrective action.

But Levin stressed, "The plan goes beyond the mere correction of deficiencies. It is designed to make the Hospital more functional in terms of its mission as a teaching institution, a base for research, a regional center for specialty care, and a comprehensive community hospital."

The report stresses the important role played by both faculty and community physicians at the Hospital:

"Each group accounts for approximately one-half the annual patient days and each group cares for patients from all of Stanford's many market areas. Both groups serve the local community, draw referrals from outlying areas, and serve secondary and tertiary care patients."

-more-

The Hospital modernization proposal recommends a two-stage approach which is interdependent and must proceed almost simultaneously.

The first stage will be an estimated $22.6 million program to complete the unfinished portion in the Hospital's new addition opened in 1976. It includes construction of a low-cost building near the Hospital to house support activities now located in the main center, and calls for remodeling the vacated space for patient care and academic needs.

This stage will correct some code deficiencies and provide needed space for cardiology, radiology, transfusion service, pharmacy, facilities department, medical records, materials storage and cafeteria.

The second stage, an estimated $70 million program, calls for construction of a new four-story wing to the north of the Hospital. This would provide 12 new operating rooms, renovation of 14 existing ones, 43 intensive care beds, 44 pediatric beds, and 56 medical and surgical beds to ease overcrowding of present wards.

At the same time all code deficienceis will be corrected.

Levin stressed the plan will not add to the Hospital's present capacity of 668 beds. "But it would create more usable beds in the main center," he said.

Financing of the Hospital proposal is under study, the report indicates. Potential funding options include a combination of long-term loans, Hospital reserves, and gifts.

If the program is approved, construction will begin in 1983 and completed in 1986.

In addition, the Hospital plan provides for renovation of the Boswell Building which houses the outpatient Clinics. In the Clinics faculty physicians treat their patients and teach medical students. Remodeling of the space is estimated at $4.5 million to be financed by a $3 million gift from the Boswell Foundation of Los Angeles, and Clinic funds.

"The clinics were never designed to meet the needs of modern medical practice," the report states. "They have inadequate waiting areas, undersized examining rooms, and major impediments to the attraction of patients and the integration of patient care and teaching activities."

The report concludes these capital outlays are necessary because of the explosive advances in medical science, the growth of clinical programs, and because the Hospital and Clinics were constructed inadequately from the start.

As an example, the report states, Stanford has slightly more than half the square footage per bed than the national average for teaching hospitals, and its operating rooms are inadequate.

"Patient care demand for greater operating room capacity is expected to increase over the next decade," the report predicts. The Hospital faces serious problems in this area with patient waiting lists, and surgeons having to operate during late hours.

"If Stanford takes no action in response to those serious problems," the report continues, "the quality of the Hospital as a teaching and community facility will decline, together with the ability to serve as a recognized base for educational and research programs.

"Failure to address cited code deficiencies could lead to decertification of beds and withdrawal of hospital accreditation which, in turn, would affect the status of Medical School programs."

City Desks: Because of the limited seating capacity of Fairchild Auditorium, the symposium on radiation exposure can be attended only by those who have registered in advance. However, members of the press wishing to cover the meeting are welcome. Advance programs are available. In addition, a press conference has been scheduled with some of the speakers Saturday, April 12 at 9:00 a.m. at Fairchild Auditorium, located just south of the Medical School. Please notify the News Bureau if you plan to attend.

STANFORD—

A symposium on the medicine of acute radiation exposure will be held Saturday, April 12 in Fairchild Auditorium of Stanford University School of Medicine.

The one-day meeting, for physicians, medical students, and other emergency health professionals, will discuss the medical implications of a nuclear reactor accident like the one which occurred at Three Mile Island.

"Based on the Three Mile Island experience, it is generally agreed that emergency planning for an accident involving a large release of radioactivity is woefully inadequate," says Roland A. Finston, Ph.D., director of Stanford University's Health Physics Department and a symposium participant.

"This meeting is designed to help physicians in Northern California who are located near nuclear power plants to understand the medical problems associated with an accident, and to make emergency plans more realistically."

The symposium, called the Irene Lenon Memorial Lecture on Environment and Health, is sponsored by the Stanford Medical Students Association and the Department of Family, Community and Preventive Medicine.

Because of limited seating capacity in Fairchild Auditorium, the symposium is open only to people who have registered in advance. Registration of those not associated with Stanford Medical Center involves a $50 fee.

The first talk of the symposium will be given by Joel Primack, Ph.D., consultant to the Nuclear Regulatory Commission's special inquiry group on Three Mile Island, and associate professor of physics at the University of California at Santa Cruz.

-more-

Primack will discuss what happens during a meltdown accident in a nuclear power plant—the mechanics of the accident, the type of radiation released, and how the radiation is distributed.

In the afternoon, Jacob Fabricant, M.D., Ph.D., director of the public health and safety task force of the President's Commission on Three Mile Island, and professor of radiology at the University of California at San Francisco, will discuss diagnosis and treatment of acute radiation syndrome in the exposed individual.

Other talks by Stanford University experts include the dosimetry, or means of measuring external and internal radiation, by Dr. Finston, the biology of radiation injury by J. Martin Brown, Ph.D., associate professor of radiology, and the pathology of acute radiation exposure by Luis F. Fajardo, M.D., associate professor of pathology.

People interested in attending the symposium should register with the Office of Postgraduate Medical Education, phone number (415) 497-5594, by April 8.

The Irene Lenon Memorial Lecture on Environment and Health is named in honor of the late Dr. Irene Lenon, a 1972 graduate of Stanford Medical School who left an endowment to the Department of Family, Community and Preventive Medicine to support medical and environmental health education.

STANFORD—

Dr. Merton Bernfield, professor of pediatrics at Stanford University School of Medicine, has been named a Macy Faculty Scholar for 1980 to 1981 by the Josiah Macy, Jr. Foundation.

The award provides support for several months of research and study in the field of perinatal biology at Yale University School of Medicine.

Bernfield plans to work at Yale with Dr. Joseph Warshaw, head of the division of perinatal medicine, beginning in August, 1980.

A graduate of the University of Illinois at Chicago, where he received his M.D. in 1961, Bernfield served as a research investigator of the National Institute of Child Health and Development before coming to Stanford in 1967.

He directed the Medical Scientist Training Program at the Medical School from 1974 to 1977, and currently directs the Fellowship Program in Molecular Pathology of Cell Membranes.

In addition to his position in the Medical School, Bernfield is Josephine Knotts Knowles Professor and Chairman of the Program in Human Biology, in School of Humanities and Sciences.

The Macy Faculty Scholar Award Program was established in 1972 to encourage medical and public health school faculty members to study in a "fresh environment."

To date, the Foundation has made 205 awards to faculty members from 67 institutions, and provided over $4.1 million in support of the program.

Recent faculty scholars from Stanford include Dr. Stanley Cohen, professor of medicine and chairman of the Department of Genetics, Dr. Eric Shooter, chairman of the Department of Neurobiology, and Dr. Irving Weissman, associate professor of pathology.

The Josiah Macy, Jr. Foundation was created by an endowment from Mrs. Kate Macy Ladd in 1930 for the advancement of medicine in the U.S.

ADVANCE FOR AM PAPERS (PST), THURSDAY, APRIL 3, 1980

STANFORD—

Toxoplasmosis, a congenital infection that has the potential of causing mental retardation, blindness and epilepsy in thousands of babies each year, can now be detected in infants, thanks to a new test developed by researchers working at Stanford University, the Palo Alto Medical Research Foundation and in Paris, France.

The new test is valuable because many infected infants appear normal at birth but most will develop severe complications later in life unless given early treatment, according to Dr. Jack Remington, professor of infectious diseases at Stanford University and coauthor of a paper describing the test, reported in the April 3 issue of the *New England Journal of Medicine.*

Remington's collaborators in the research were Stanford postdoctoral scholar Dr. Christopher B. Wilson and Drs. Jacques Couvreur and Georges Desmonts of the Institut de Puericulture in Paris.

With the new diagnostic test, drug treatment can be started in early infancy, significantly reducing chances of later serious complications, Remington explained.

The new test, called lymphocyte transformation, takes advantage of the fact that even unborn infants have an active immune system, he noted.

Lymphocyte cells in the infant's blood become sensitized to chemical markers called antigens, from the *Toxoplasma* organism.

When the sensitized lymphocytes come in contact with the antigen, they divide rapidly to bolster the body's immune attack. This rapid division can be detected by simple laboratory techniques in blood samples taken from the infant, Remington explained.

A positive result "can be regarded as strong evidence of congenital *Toxoplasma* infection both in symptomatic and asymptomatic children three months of age or older," the researchers wrote.

Previous tests were neither sufficiently reliable nor speedy in diagnosing toxoplasmosis in infants younger than one year of age, according to Remington, who is head of the division of allergy, immunology and infectious diseases at the Palo Alto Medical Research Foundation.

-more-

The infection is caused by a parasite, *Toxoplasma gondii*, that chronically infects almost 50 percent of the U.S. population and is usually harmless and unnoticed in adults.

About 25 percent of women in the child-bearing age group in the U.S. harbor the organism in their bodies. In them, the infection poses no threat to the fetus.

But when acquired during pregnancy, 45 percent of the time the parasite passes to the fetus where it may cause significant damage to vital organ systems, the doctors said.

In one study conducted by Remington, Wilson and colleagues, 92 percent of the infected infants under investigation later developed complications, including retardation, seizure disorders, and eye disease or blindness in one or both eyes.

The common house cat frequently spreads the infection.

The primary ways pregnant women become infected are by eating raw or undercooked meat, and by contact with stray cats, infected house cats or material likely to be contaminated by cat feces.

Simple precautions for pregnant women to follow could also go a long way towards control of the disease, the researchers stressed.

These precautions include avoiding raw and rare meat by smoke-curing or cooking above 66 degrees centigrade, washing hands after handling raw meat, avoiding contact with stray cats, letting someone else change the cat litter, and avoiding work in the soil or gardening without gloves.

Approximately 3,300 infants born each year in the United States are congenitally infected with *Toxoplasma*, and cost analysis estimates suggest that society pays up to $221 million for care of individuals born each year who develop complications, Remington said.

Although the lymphocyte tramsformation test has been used to diagnose certain diseases in adults, this is the first demonstration of its effectiveness in detecting congenital disease in infants, the researchers said.

The research was carried out under grants from the National Institutes of Health.

STANFORD—

"Twenty years ago we regarded DNA as a rigid, rod-like molecule," said Nobel Laureate Arthur Kornberg. "We thought of DNA as being simply a construction manual responsible for the cell structure and the enzymes that made the cell work.

"Another function of DNA was to be replicated so that a daughter cell would have the same construction manual with which to assure the life-style that its parent had."

Today this image of DNA has changed.

"We know now that DNA is a molecule with considerable flexibility and plasticity," he said. "Its dynamic behavior involves many functions."

"Anything that you can imagine about DNA can be used somewhere in some way," commented Dr. David Baltimore, a professor of microbiology at the Massachusetts Institute of Technology.

Baltimore was summing up a review of 20 years of work in DNA research which had been detailed at a two-day symposium March 27 and 28 by Stanford University Medical School scientists who have been leaders in the field: Dr. Kornberg, Dr. Paul Berg, Dr. David Hogness, Dr. Robert Lehman, and Dr. Stanley Cohen.

Lehman said that after 20 years a great deal is now known about the repair of DNA. "A very important generalization is that there is no single mechanism for the repair of DNA in any given cell," he said. "There are many mechanisms for the repair of damage caused by environmental insults such as ultraviolet radiation, gamma and x rays, and chemicals."

In retrospect this should have been fully anticipated, Lehman noted. "The preservation of the genetic material is so crucial to the life of the cell that it is reasonable for cells to have evolved a fail-safe mechanism—back up systems to take over when others fail."

DNA stands for deoxyribonucleic acid. It is the stuff of which genes and chromosomes are composed as the bearers of heredity in all living things.

The term "genetic recombination" discussed at the symposium refers to the process by which genes are reassorted and new linkage relationships are established between them.

"Recombination permits an organism to try out a number of arrangements of its genes in search of those which give optimal selective advantage," Lehman explained. "It is therefore a major driving force in evolution."

While scientists have learned a great deal about the repair mechanisms of DNA, knowledge about the molecular aspects of recombination still lags behind, he said.

In the past two decades, Stanford has been one of the nation's leading DNA research centers, so much so that Baltimore told the symposium participants, "You can imagine that all molecular biology comes from Stanford. I guess I am here to say that the rest of the world still exists."

Kornberg and the other scientists used slides to illustrate the elegant maneuvers and chemical steps used in their work. They showed how DNA can be spliced, cloned, and separated in specific parts or glued together.

He recalled that for years after James Watson and Francis Crick discovered the double helix in 1953, the processes of DNA replication remained a mystery.

To illustrate his point, Kornberg showed a colleague's humorous cartoon picturing the DNA molecule obscured by a fig leaf.

"I confess this slide did have a psychological impact on me," he said.

-more-

In 1967, Kornberg's group was confronted with the task of whether an important enzyme DNA polymerase could copy a strand of DNA without error, making a gene or a collection of genes—a chromosome.

"We were pleased to report," Kornberg said, "what the news people rather prematurely called the creation of life.

"In fact, not only was there local excitement, but President Johnson called to congratulate us. At the time we did not fully appreciate that it was a more complex process."

After more than 10 years of painstaking research a lot has been accomplished. "We have removed the fig leaf and we are looking at the machinery of replication," Kornberg said. "We still don't know, however, where the process starts. We would like to know more about the origin of the cycle of replication."

In recent weeks, he added, work at his laboratory had produced evidence that the "locomotive" that drives replication moves in a certain direction on the DNA strand. This is a step toward understanding the "gearing up" process.

Hogness, a professor of biochemistry who is studying the genes of the fruit fly, described molecular cloning techniques which have yielded many surprises concerning the organization, structure and expression of genes.

He said, "The research has the potential of answering the most fundamental and appealing questions of biology. This is how the genes direct development."

Other presentations during the two-day meeting included reports on the isolation of new types of highly specific antibodies, research on the roles of immune mechanisms and disease, the architecture of antibody molecules, the relations between heredity and culture, and advances in the neurosciences.

Progress in clinical medicine included reports b Dr. Henry S. Kaplan, professor of radiology, who described how the once-fatal cancer called Hodgkin's disease can now be often cured, and by heart transplant pioneer Dr. Norman E. Shumway who said the success rate of heart transplants is now as good as those of kidney transplants.

In addition, techniques of Total Lymphoid Irradiation (TLI), developed by Kaplan, are now used to alter the immune system of man and animals allowing for the acceptance of organ transplants, and the treatment of patients with autoimmune diseases such as rheumatoid arthritis.

The sessions concluded with remarks by Nobel Laureate Joshua Lederberg, president of Rockefeller University.

Lederberg called Stanford's clinical achievements "the ultimate payoff in an exciting game, the pursuit of science."

People in biochemistry, physiology, internal medicine, and other fields, all are looking for answers to the same things from a slighly different perspective, he said.

"All of the major problems in human health are wrapped up in the DNA," Lederberg commented. "They include developmental defects, genetic defects, psychiatric diseases, some elements of heart disease—you name it."

Baltimore predicted that it will be possible to understand cancer, genetic diseases, and probably aging. "But what we do with that knowledge will depend on the health of the scientific enterprise," he said.

"We need institutions dedicated to the acquisition of knowledge and to the training of people who keep up with the changing technologies as well as the theoretical basis that allows for progress into new areas," he added.

The symposium marked the two decades that have elapsed since the Medical Center, once located in San Francisco, moved out of its former headquarters on Clay Street, and was relocated to the main Stanford campus.

ADVANCE FOR P.M. RELEASE SATURDAY, MAY 31.

STANFORD—

Success in developing an "artificial ear" for the totally deaf now hinges primarily on "cracking the code" of electrical pulses on the auditory nerve by which the ear conveys speech information to the brain, according to a Stanford University scientist.

"We have come a long way now on developing the technology necessary for the small, low power, long-lived electronics required for the artificial ear. I am convinced we can solve the remaining technological problems within the next two years," said Professor Robert White, Director of the Institute for Electronics in Medicine at Stanford.

"The hardest part now is determining just how to pattern the electrical pulses on the nerve so that the brain will interpret them as speech and extract the speech information," he said.

White spoke on the development of an artificial ear device by Stanford scientists at the fourth annual conference for alumni of the School of Engineering on Saturday, May 31 at the University's Terman Engineering Center.

The device, one of several being developed throughout the world, is designed to bypass defects or injuries in the inner ear which have resulted in total deafness, White said.

"We are in effect attempting to trick the brain into thinking the ear is working when actually it is not," he said.

The device consists of an external box which converts sound into electrical signals and transmits them across the skin into the mastoid cavity above the ear. There, a surgically-implanted receiver and neuro-stimulator the size of a quarter sends electrical impulses down a series of electrodes to the auditory nerve.

It has been known for 200 years that stimulation of the auditory nerve will produce the perception of sound, White said, but only with the recent explosion in integrated circuit technology did it become feasible to exploit this phenomenon to try to "cure" deafness.

White's co-investigator is Dr. F. Blair Simmons, a professor of surgery (otolaryngology) at the Medical School who is one of the pioneers in the artificial ear field, he said.

Simmons performed one of the first multi-wire implantations in a patient in 1965. "His publication on this work is one of the landmarks of the field," White said.

However, inadequate technological backup limited progress on the project at that time.

-more-

White joined Simmons in 1972, the year the project received its first grant from the National Institute of Neurological Diseases and Stroke.

In the intervening years, the two scientists and their colleagues developed a four channel (electrode) device, which Simmons implanted in two deaf subjects in 1977.

Although the current model does not provide enough information to give the subjects unaided speech perception, it does give significant speech cues, and has improved their ability to read lips, White said.

In addition, the device provides "auditory clues" which enable them to recognize that the phone is ringing, or that someone is knocking on the door.

Similar devices are being implanted in patients at other centers, White said, and at least one company is gearing up to produce a fairly simple single channel system within a year, under the rationale that such devices provide useful, if limited, auditory input to people who previously lived in total silence.

The Stanford group, however, is not satisfied with that. "Essentially all our work has been directed toward giving full unaided speech comprehension," he said.

Currently, the Stanford group is working on an eight channel device which will provide a precisely timed sequence of electrical signals at different points on the auditory nerve.

Hopefully, the electrodes will play the right "keys" in the brain in the right sequence so that subjects will be able to discriminate speech, White said.

Major difficulties have included developing low power custom integrated circuits, a hermetically sealed "can" which will protect the device from a hostile and corrosive environment inside the body, and electrode arrays which can bring signals to precise locations on the auditory nerve without damaging it.

These components are now in the testing stage, and the completed device "may be ready for implanting in subjects this Fall," White said.

White can be reached at (415) 497-4431

STANFORD—

The director of Stanford University's Heart Disease Prevention Program Thursday criticized a panel of the National Academy of Sciences (NAS) and its recommendations on diet and health as "unnecessarily conservative."

"Although I agree with many of the panel's views," said Dr. John W. Farquhar, "I must disagree with the notion that diet guidelines should be applied only to people at high risk."

Farquhar, a professor of medicine and a member of the Institute of Medicine of the NAS, said that having only some groups following dietary guidelines would be a losing battle.

He said some people believe that all you have to do to solve a medical problem is to identify the people at risk and give them advice.

"From the standpoint of effectiveness of public health this does not work," Farquhar said. "We do not have enough doctors to identify all of those at high risk and change must involve all family members in order to work."

Farquhar made his comments after news reports of the Food and Nutrition Board were published yesterday.

The panel, which develops the Recommended Dietary Allowances of vitamins and nutrients used by the government and food industry, questioned the validity of guidelines for low-cholesterol, low-saturated fat diets to prevent heart attacks.

The panel said it has not been scientifically proven that lowering the levels of blood cholesterol through diet will consistently reduce new coronary artery disease, although there may be a benefit for high-risk people.

But Farquhar took issue with the statement saying that it would be perceived as a switch in diet advice for Americans.

And he added, "I am worried about some 15,000 people around the country who have volunteered to participate in studies designed to clear up the relationship of fat diet and heart disease. Their nutritionists and the scientists who take care of them will have a lot of explaining to do."

Farquhar, who serves on the Nutrition Committee of the American Heart Association, said that available data strongly support the need for lowering fat intake in diet as a reasonable national goal.

"Although as scientists we would like to know a lot more about heart disease," he said, "most groups agree it is not necessary to have all the pieces of the puzzle before one could devise coherent action."

He said most public health educators are in agreement that to be effective you have to apply diet guidelines to an entire population—not a single group. This means guidelines will help some people more than others.

"The panel obviously wants to stand out as an exception," Farquhar said, "but this should allow for their recommendations to come under scrutiny and to accept the contrary opinions of other people who have worked in this field."

Farquhar said diet guidelines now advocated by the American Heart Association and federal agencies were developed as a result of three types of evidence.

One of these is observational epidemiology. "As you look about the world you find that cultures eating a lot of animal fat have higher cholesterol levels and incidence of heart disease than cultures that do not," he explained. "That in itself does not prove cause and effect, but just as the evidence with cigarettes and cancer, it makes us think.

-more-

"The second line of evidence comes from experiments in which certain human populations are made to lower their cholesterol and you find that the rate of heart disease has been reduced.

"The third type of evidence comes from animal studies showing that when you reduce cholesterol, the rate of narrowing of the coronary arteries also drops."

Farquhar noted that there has been a 22 percent reduction in heart attack mortality in the United States, Canada, and Australia since 1967.

In all three countries there has been a reduction in all three risk factors—high blood pressure, cigarette smoking, and the levels of blood cholesterol.

It is possible that other factors such as better coronary care units, use of antiarrhythmic drugs, and coronary bypass surgery are responsible for the lower death rates, Farquhar said.

"But most scientists feel that these things alone cannot account for all of the decline."

He said overall the evidence makes a strong case for diet.

More recently, Farquhar said, new evidence has come to light, although still inconclusive, that high fat animal diets may play a role in breast and colon cancer.

"People who are conservative on the diet issue and heart disease prevention are going to have to reckon with all that evidence later on," he said.

The country as a whole might need 10 years or more to get accustomed to the importance of low-fat, low-cholesterol diet, he added. "So I think the panel's report may cause temporary confusion, but will also lead to a useful debate on this important topic."

Farquhar, author of a book, *The American Way of Life Need Not Be Hazardous to Your Health,* has directed the federally funded three communities study in Northern California for the past eight years.

The study, using mass media, has shown statistically that when people are given proper information about themselves they can make sound judgments in order to improve their health.

STANFORD—

Neighbors on Roxanne Drive in San Jose are giving "a gift from the heart" in a unique memorial tribute to a friend who recently died.

"The family expressed the wish that blood donations be made to the Stanford University Blood Bank in memory of Jack Merriam," said Mrs. Becky Bright of Roxanne Drive, a close neighbor of the bereaved family.

Mrs. Bright contacted the Stanford University Blood Bank, which will set up a mobile blood donation unit on June 8 at the Image Center, 1610 Blossom Hill Road, Suite 5, San Jose, between noon and 5 p.m..

"The blood drive is our way of getting together to show the Merriam family our sympathy and to show how much we care," Mrs. Bright said.

This will not only replace the 20 pints of blood used during his care at Stanford University Hospital, but will also help other heart patients presently at Stanford, she added.

"The concept of a memorial drive is a unique and generous one that we are pleased to participate in," said Rhoda Burns of the Stanford University Blood Bank.

Those interested in donating may make appointments by calling Mrs. Bright at (408) 267-4101. For information on eligibility to be a blood donor, call the Stanford University Blood Bank at (415) 497-7831.

STANFORD—

Relatives of cancer victims at Stanford University Hospital now receive a short course in home nursing so that they can care for the individual after leaving the hospital.

The six-hour course is offered by the Palo Alto Chapter of the American Red Cross, and family referrals to participate are coordinated by Isabel Walker, social worker, and Barbara Reville, R.N., of the Stanford Oncology Day Care Center.

"We are starting to open a new way of training families or friends to become the support system for the cancer patient at home," Mrs. Walker explained.

Stanford's Oncology Day Care Center provides chemotherapy to patients with cancer on an outpatient basis. When complications arise a patient is hospitalized for a short time and then is able to return home. As Stanford has no hospice program, Mrs. Walker feels this new endeavor is an attempt to "extend services to the home using existing community resources."

"Relatives often feel helpless when things seem to be out of theri hands," Mrs. Walker said. "They need information and reassurance."

An example of how the program works is Mrs. Joan McVicker of Fremont, Calif. Her 18-year-old, Lori, has a form of cancer called lymphoblastic lymphoma and was treated at Stanford.

Just before Lori went home, Mrs. McVicker took the Red Cross course, and she became her daughter's nurse.

"I felt so confident, I thought I can now cope with anything," Mrs. McVicker said.

She was trained to give Lori her medications, to take her temperature and blood pressure, to give her bed baths, to monitor her nutrition and to do all the things a home nurse would do.

"Lori had problems swallowing her medications," Mrs. McVicker said. "Everytime I gave her a pill she would choke."

The Red Cross taught her how to take two spoons, crush the pill between them, and cover it with apple sauce, she said.

"The pills now slide down easily and I am no longer scared."

Cancer patients today spend various phases of their illness at home, explained Mrs. Walker. They need a comfortable environment, medication to alleviate pain, sometimes exercise, good nutrition to sustain their weakened bodies, and most of all—tender loving care.

-more-

"Only the family can give these," she said. "But not all families are equipped to cope with the emotional and physical needs of the cancer patient."

That is where the Red Cross is a big help. And now, with the increasingly high cost of health care in hospitals, home health care is viewed as an attractive alternative.

But even more important is that we can reduce the feeling of helplessness," Mrs. Walker said. "Cancer is a family affair. People cannot have cancer and be left alone."

The idea for the program came from Mrs. Walker's experience as a public health nurse, and as an instructor for the American Red Cross in the 1950s. The Red Cross has been the pioneer in programs of home nursing since World War I.

Mrs. Walker and Ms. Reville surveyed relatives of cancer patients in the Oncology Day Care Center. They found interest in home care was high and they contacted the Red Cross.

The home nursing course is taught each month by a volunteer R.N., Verla McMorran, at the Palo Alto Red Cross Chapter. Instruction starts with a film, and includes such topics as body mechanics, oral hygiene, nutrition, and how to give a bed bath, medications, keep records, and when to call a doctor.

In addition, Mrs. Walker includes a section on the psychosocial aspects of living with cancer.

The course is free of charge, except for the textbook, *Family Health and Home Nursing*, available from the Red Cross for $3.95.

The program is evaluated regularly to find out if it meets the needs of patients at home. Evaluations include both group sessions and written forms. From this feedback, improvements are planned for future courses.

"We learn that families are using what they have been taught and feeling good about it," said Ms. Reville.

But the course, according to the families, has auxiliary benefits too.

"When I took it, I felt I was the only person facing a loved one with cancer," said Mrs. McVicker. "A lot of other people were there for the same reason. We had a special bond, and I felt much better."

The next course will be given June 7 from 9 a.m. to 3 p.m. at the Red Cross, 400 Mitchell Lane, Palo Alto. Persons interested in signing up should contact the Red Cross at (415) 322-2143, or the Oncology Day Care Center at Stanford at (415) 497-7621.

CITY DESKS: The press is welcome to attend the sessions, but the meeting is limited to Stanford medical alumni only.

STANFORD—

Scientific and clinical accomplishments of Stanford Medical School graduates will be the theme of the 1980 alumni-faculty reunion Saturday, May 31 in the School's Fairchild Auditorium.

Dr. Donald Kennedy, Stanford's vice president and provost, and former commissioner of the Food and Drug Administration, will give the keynote address at a noon luncheon—"Regulation and Health: Two Decades of Change."

This year's reunion is held in connection with the 20th anniversary of the School's move from San Francisco to Palo Alto. A clinical symposium in the morning will be given by members of the classes of 1959 through 1964.

The symposium, which begins at 9 a.m., will be an updating of progress in frontier areas of medicine and biology.

Stanford's medical school has long been known for its emphasis on training physicians who plan to pursue careers in research and teaching as well as clinical medicine.

Thus, the alumni symposium focuses on the work of Stanford graduates who were taught in the School's world famed departments during the past two decades. An earlier symposium held this year dealt with the work of Stanford faculty in fundamental and applied research.

The talks from 9 to 10 a.m. include: "Computers and Clinical Judgment" by Marsden Scott Blois of the University of California, San Francisco; "Some Genes Come in Big Doses" by Laurence H. Kedes of Stanford; and "Pathogenesis and Treatment of Diabetic Retinopathy" by Hunter L. Little, a practicing eye specialist and Stanford clinical professor.

The presentations from 10:55 to 12 noon include "Brain-Evoked Potentials and Their Use in Evaluating Patients with Head Injury" by Maurice Rappaport of the Langley Porter Neuropsychiatric Institute in San Francisco; and "Use of Electron Microscopy in the Rapid Diagnosis of Viral Infections" by Nelson A. Wivel of the National Institutes of Health, Bethesda, Maryland.

Dr. Alvin Cox, professor of dermatology emeritus, will discuss the historical ties of the School to its predecessor in San Francisco at a special session at 3 p.m..

Reunion dinners for various classes will be held in the evening.

STANFORD—

The old-fashioned house call lives on at Stanford University Hospital under a new name—home care.

Like many other hospitals throughout the U.S., Stanford is placing a greater emphasis on providing care at home, rather than in a specialized health facility, according to Liza Taft, R.N., director of the hospital's discharge planning program.

The purpose of home care is to preserve as much patient independence as possible, she said, but in many cases it has the added advantage of cutting the patient's medical bills.

At Stanford, home care is organized by a team of health professionals who begin planning for the patient's discharge almost as soon as he or she is admitted.

"Discharge planning" may involve prescribing physical therapy, so patients can recover needed body strength, teaching them how to take their own medications, or lining up a variety of support services outside the hospital, such as Meals on Wheels, part-time household help, and visiting nurses and physical therapists.

Some of these services are organized under the auspices of hospitals or county health centers. Others are independent. Many of the services are reimbursable under Medicare, MediCal or other insurance programs, but even when they are not, they can be less expensive than hospital care.

For example, Taft said that a home care visit may cost $45 and nursing care may run $10 to 15 an hour, compared with an average hospital charge of $200 daily.

Sometimes just providing information may mean the difference between resuming life at home after a period in the hospital, or institutionalization.

Taft recalled the case of a 74-year-old woman who lived in a mobile home with her elderly husband. While in the hospital, her doctor told her that he felt she could no longer care for her husband, who suffered from heart disease and diabetes, and recommended that they both move to a nursing home.

"She called me to talk about it," Taft said, "and I suggested she look into a variety of services that would allow her to remain at home.

"I don't know what would have happened if I hadn't talked with her," she added.

Although the discharge planners deal increasingly with older patients, referrals are also required for mothers and young patients.

For example, "we've helped design a rehabilitation program for a 10-year-old quadriplegic, and we've helped arrange home nursing care for the sick newborn of a single mother who has two other children under three years old," Taft said.

"These cases are not that much different from that of the 74-year-old," she added. "The idea is to keep the family intact."

One of the most dramatic examples of home care is the hyperalimentation training program.

Hyperalimentation refers to the tube feeding of people who because of disease or injury cannot absorb food normally. A carefully balanced and highly concentrated mixture of salts, sugars and proteins is fed by catheter directly into the heart, where it is quickly diluted and distributed throughout the body.

-more-

Ten years ago, this treatment had to be administered by physicians in the hospital. Today, patients at Stanford hospital are taught to feed themselves, then sent home.

Jerry Nessel is one of five patients who have been trained in home hyperalimentation sinced the program began one and a half years ago.

A victim of cancer of the colon, which prevents him from eating solid food, Nessel had been in the hospital for three months when he began his training.

Under the direction of physicians, a team of nurses and pharmacists taught him how to keep the end of the catheter which is exposed to the air sterile and free of infection. They taught him how to prevent blood clots from forming inside the catheter with the use of heparin, a blood thinner. And they showed him how to mix the solutions and connect them to a machine which pumps them into his body.

Now at home, Nessel is very grateful to "be in my own surroundings, in touch with friends.

"The cooperation of my physicians, nurses and pharmacists at Stanford was exemplary," he said. "They pulled me through. They put me on my feet again and sent me home."

Pharmacist Tim Cheung, who is primarily responsible for the home hyperalimentation teaching program at Stanford, said that in addition to giving patients back their independence, the program saves money. It costs about $150 a day to rent the equipment and buy ready-mixed solution at home, compared with $300 a day to receive the same treatment in the hospital. And if patients mix their own solutions, the cost drops to $60 to $70 daily.

Planning for the patient's discharge requires the team effort of physical and occupational therapists, social workers, pharmacists, nurses, doctors, and dieticians. For difficult cases, these health professionals find it is useful to structure their efforts as a team in weekly meetings.

A coordinated rehabilitation program, directed by Gladys Kurzuk, R.N., is available to all stroke patients in the hospital.

On the hospital's orthopedia unit, this "co-care" program has been adapted for the rehabilitation of patients who have sustained major trauma and whose care requires the involvement of several team members.

Each Tuesday morning, the rehabilitation team meets to discuss patient problems and establish a consistent and comprehensive patient care plan. The patient and his or her family are encouraged to participate by using a bedside calendar and with the assistance of the patient's primary nurse. In addition, patient and family are asked to attend the rehabilitation program meetings whenever possible.

"In the past, we all went about our duties without knowing what the others were doing for the patients," said clinical nursing coordinator June Ogilvie, R.N., who organized the program.

The meetings enable all of the team members to work cooperatively and efficiently toward a designated release date. "This can't help but improve the independence of patients, if only by increasing their involvement in their own rehabilitation," she said.

STANFORD—

Dr. J. Martin Brown, associate professor of radiology at Stanford University School of Medicine, has won the 1980 Radiation Research Society Research Award.

The award, which is given annually by the Society for "outstanding contributions in radiation research," consists of a citation and $1,000.

Brown will receive the award at the Society's annual meeting in New Orleans on June 2.

A native of England, Brown received his D. Phil. in radiation biology at Oxfold University in 1968, then came to Stanford as a post-doctoral fellow and joined the faculty in 1971.

He is well known for his work on radiosensitizers, certain agents which can preferentially enhance the effects of radiation on cancers compared to normal tissues, and for his evaluation of the possible carcinogenic hazards of radiation.

Brown is a member of numerous scientific committees, including the National Academy of Sciences' Advisory Committee on the Biological Effects of Ionizing Radiation, and has authored over 60 scientific papers.

STANFORD—

Individuals who suddenly have their oxygen supply cut back (from respiratory failure or certain other conditions) may become sick or die, but patients with chronic diseases that lower their oxygen intake can adapt and survive, according to a Stanford University professor of medicine and physiology.

The harmful, often fatal, effects of oxygen depletion in the body, and the cellular adaptations that may permit living things to overcome and survive these conditions were described Tuesday, May 20 by Dr. Eugene Robin, the 1980 Amberson Lecturer at the annual meeting of the American Thoracic Society in Washington, D.C..

Robin noted that the condition of low oxygen supply in the body, called hypoxic dysoxia, is one which has not been carefully explored and studied until recently.

Understanding adaptation to lowered oxygen supply could help in developing new ways to treat patients with acute oxygen depletion, Robin suggested.

Much of the damage caused by oxygen depletion in humans and other animals is due to the disruption of normal biochemical reactions that take place inside living cells, Robin said.

These biochemical reactions involve energy production that "is used to move our muscles, permit our heart to beat, our glands to secrete, and our brain to think creative and productive thoughts," he explained.

Some animals display a remarkable ability to lower their energy requirements when low levels of oxygen are present in their bodies.

The freshwater turtle is one example, said Robin, with its "ability to dive for hours to days despite a fall in lung, blood and tissue oxygen to values of zero."

An adaptation enabling turtles "to reduce cell energy requirements by about 75 percent during the dive helps them accomplish this remarkable feat," he said.

Lower nervous system, cardiac and skeletal muscle activity go along with the reduced energy needs, he added.

Robin and his colleagues have observed similar reductions in energy requirements during prolonged diving in seals, and the mammalian fetus is thought to have a similar ability to lower its energy needs.

More work is needed to discover how animals accomplish this reduction of their energy needs.

However, new techniques for measuring biochemical reactions inside cells will become feasible in the next several years, Robin said, and these may be useful in the study and treatment of patients with hypoxic dysoxia.

Robin is professor of medicine and physiology at Stanford.

The Amberson Lecture was established in honor of J. Burns Amberson, a leader in the field of respiratory diseases. Lecturers are selected from those who have provided outstanding scientific contributions in the field of respiratory medicine.

STANFORD—

"Strategies for change—group therapy and hypnosis" will be the topic of a free public lecture at Stanford University School of Medicine on Thursday, May 29.

The lecture, sponsored by the Friends of Psychiatry and Behavioral Sciences, will be held at the Medical School's Sherman Fairchild Auditorium beginning at 8 p.m.

Speakers include Drs. Irvin D. Yalom, professor, and David Spiegel, assistant professor in the Department of Psychiatry. Department chairman Dr. Thomas A. Gonda will serve as moderator.

Yalom is a prominent researcher in the field of group psychotherapy. His book *The Theory and Practice of Group Psychotherapy* is considered a classic text in the field.

He also is noted for his studies on the relationship of hormones to behavior and the counseling of dying patients.

Spiegel, who directs the social psychiatry and community services at the Palo Alto Veterans Administration Medical Center, is well known for his work in hypnosis. He is co-author of the book *Trance and Treatment: Clinical Uses of Hypnosis.*

How genes are reproduced and repaired will be the topic of the last spring Progress in Medicine lecture on May 20 at 7:30 p.m. in Fairchild Auditorium at Stanford University Medical Center.

Dr. Errol Freidberg, associate professor of pathology, will describe the techniques cells have developed for repairing damage to DNA, the hereditary material of living things. He will also discuss the relationship between DNA repair and malignant cell growth.

Dr. David Korn, professor and chairman of the department of pathology, will describe how DNA is replicated inside cells, and he will discuss the enzymes involved in the replication process.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine, the Stanford University Hospital, and members of the Medical Center Council.

An "information day" on critical care nursing will be held at Stanford University Medical Center on Wednesday, May 21.

The program, sponsored by the Department of Nursing Service, is for nurses who want to learn more about nursing specialties at Stanford, including care of heart transplant patients, advanced life support and emergency care, and transport of critically ill infants and adults and high risk mothers.

Tours will be conducted on all intensive care units, and poster exhibits in Fairchild Auditorium will describe aspects of various technologies, patient education and nurse orientation.

The day-long program begins at 8:30 a.m. in the auditorium, located just south of the Medical Center.

Speakers include Dr. Myer Rosenthal, medical director of the intensive care units, Dr. Kent Ueland, chief of maternal and fetal medicine, Dr. Norman Shumway, chief of cardiovascular surgery, Dr. Jay Mason, assistant professor of medicine, and Ann Baldwin, Ph.D., R.N., a nurse consultant specializing in ways to manage job stress.

Lunches will be provided.

Nurses interested in attending the program are urged to contact the Department of Nursing, at (415) 497-5181. Space is limited.

STANFORD—

"Runners make good lovers."

This is the opinion of Dr. Peter D. Wood, a lean, balding professor at Stanford University School of Medicine, and one of the finest senior distance runners in the country.

Wood postulates the "sexual athlete," capable of virtuoso performance, is pictured as a fit, slim, vibrant individual, not as obese, wheezing, or out of breath.

"Since sex may, rather narrowly, be regarded as a pleasant athletic diversion, then a pair of physically fit players is most likely to put on a good performance," he says.

"Good sexual performance calls for good physiological equipment and psychological attitude. Running seems to offer both attributes to both sexes.

"Running has features that make it an erotic activity. The customary clothing is revealing, but not unduly so. The movement involved is intriguing."

Wood adds, "I suspect countless men have enjoyed running behind a shapely woman. Voyeurism, you could say, I suppose. But this is a pleasure denied to sedentary man."

A certain amount of female bottom slapping has been observed on the part of some mature male runners, at least in uninhibited California, he reports.

Wood expresses his thoughts in a new book, *Run to Health* (351 pages, Charter Books, New York, 1980, paper $2.50).

The book, drawn from his experiences as a runner and as deputy director of Stanford's Heart Disease Prevention Program, is a whimsical guide to everything you wanted to know about running but were afraid to ask. His topics on the heart, cholesterol, weight, smoking, and running risks are drawn from his scientific work at Stanford.

But Wood makes it clear that his comments on the sexual aspects of running are more philosophical than scientific. "After all nobody has written a Kinsey Report on runners, though the readership is there."

On the more serious side, Wood's book provides valuable health advice for the novice runner if he or she wants to survive and to make it safely to the bedroom. Among his recommendations:

•The runner is usually most comfortable running when he has eaten lightly or not at all, in the previous three to five hours.

•Water is the only dietary component that may become in critically short supply during even quite long runs. It should be replaced during and after runs, particularly in hot or warm weather.

•Diluted glucose-containing drinks may be helpful in the later stages of longer runs.

-more-

Wood comments the most healthy diet for runner and nonrunner alike is the well-known formula: low in saturated fat, cholesterol and salt, and moderately high in starches. Yet there is evidence that "carbohydrate loading" does increase the glycogen content of leg muscles, and this technique may improve running performance over distances of 15 miles or more.

"The dedicated runner," Wood observes, "although much leaner than average, eats more of all foods than the sedentary individual, to balance his high energy expenditure. Runners do eat more but weigh less.

"The runner does not require supplementary vitamins and minerals, with the possible exception of iron in women.

"Vegetarian diets have excellent health features and are compatible with good running performance if carefully selected.

"Constipation is seldom a problem in the regular runner, especially when combined with a diet containing adequate fiber."

Wood explains the runner's blood is different from the blood of relatively inactive people and is perhaps his most valuable possession. The runner's oxygen-carrying red blood cells are renewed more frequently and are often present in lower concentration in the blood than that of sedentary persons.

"Although the runner's total cholesterol level is not much different from average," he explains, "we know now that runners display a remarkably healthy-pattern of plasma lipoproteins, the minute fat and cholesterol-containing particles involved in the integrity, or downfall of our arteries."

Of women runners, he says, "They not only enjoy running but are now performing very well, especially over the longer distances.

"Running offers many benefits to women of all ages—weight control, a good figure, freedom from smoking, great cardiovascular fitness and improved rapport with the family."

There is rapidly mounting evidence, Wood concludes, that running can confer much sought-after health benefits. Running is preventive medicine!

"Running entails some risks," he says, "but overall the runner has many characteristics of the fit, healthy human being, the darling of the life insurance companies."

"And runners are also nice people," he smiles. "This has always been axiomatic in my household."

Wood first felt the urge to run in London in 1935, when a race for six year olds was held on the occasion of the Silver Jubilee of King George V and Queen Mary.

"In those days it was important for every British boy to have a sport," he recalls. "Running wasn't as popular as it is now, but I managed to survive every urge to quit."

Ironically, Wood's research is now concerned with the influence of exercise on cholesterol levels and HDL, the newly discovered blood component that seems to protect against heart disease.

He wrote *Run to Health*, he says, to stress the positive effects of exercise, and to clarify the confusion surrounding the benefits and difficulties one encounters in becoming a runner.

STANFORD—

Patricia Taylor, R.N., assistant director of the Emergency Department, has been named the 1980 Thomas A. Gonda Employee of the Year at Stanford University Hospital.

A member of the Emergency Department staff for the past 17 years, Taylor's "dedication to the institution is known to everyone who has come into contact with her," said Dr. Michael Eliastam, director of Emergency Services.

She has been a leader in training and recruiting critical care nurses for the department, in reorganizing the department facilities and services "while remaining a skilled bedside nurse who delivers the highest quality patient care and maintains our goal of the patient first," Eliastam added.

Taylor was presented with the award by Hospital Administrator Gary Mecklenburg during the Hospital's 22nd annual awards banquet at Rickey's Hyatt House May 9.

Four other Hospital employees were presented with special service awards for outstanding performance, initiative, creativity and leadership in their jobs.

They are Joyce Lawson, chief radiation technologist, on the staff for 24 years; Jessie Butler, laboratory assistant in the clinical labs, a 30-year employee; John Silva, courier driver for the past 10 years between the Main Center of the Hospital and Hoover Pavilion; and Marianne Rosson in accounts receivable, who has been with the Medical Center for 15 years.

Nurse Marguerite Brickner, R.N. was given special acknowledgement as the Hospital's longest-term employee, with 35 years on the staff.

Altogether, 267 employees were awarded pins for 10 to 35 years of employment, representing a total of more than 4,000 years of service to the Hospital and Clinics.

A large turnout of employees and their guests joined the banquet festivities, which included remarks from Dr. Lawrence G. Crowley, acting dean of the Medical School and vice president for medical affairs.

Taylor is the fifth recipient of the Hospital's Employee of the Year award. Established in 1975, the Gonda award honors Dr. Thomas A Gonda, former director of Stanford Hospital and currently chairman of the Department of Psychiatry and Behavioral Sciences in the School of Medicine.

ADVANCE FOR P.M. RELEASE SATURDAY, MAY 10, 1980

STANFORD—

Stanford University physicians have reported "significant improvement" in the surgical treatment of abnormal heart rhythms (arrhythmias) with the use of a new technique.

The technique, called activation sequence mapping, relies on placement of electrodes inside the patient's heart to pinpoint the source of the arrhythmia.

Surgery, to interrupt the abnormal rhythms, can then be performed more accurately.

The work was reported Saturday, May 10 by Dr. Edward Stinson, Doelger Professor of Cardiovascular Surgery, and Dr. Jay Mason, director of the Stanford Cardiac Arrhythmia Study Unit, at a three-day international symposium on cardiac arrhythmias sponsored by the Medical School's division of cardiology.

The techniques for mapping and surgically treating arrhythmias were pioneered at Duke University about a decade ago, Stinson said. However, they are just beginning to be used widely.

Stanford's program began only within the last six months, but preliminary results, in a series of 20 patients with heart disease, are encouraging, he said.

Mason compared results in 32 patients with severe arrhythmias not treatable by conventional means, who underwent surgery without prior mapping, to 20 patients who had surgery with mapping.

Complete success was achieved in 85 percent of the mapped group, while only 19 percent of the unmapped group were completely free of arrhythmias after surgery.

One patient in the mapped group and nine in the unmapped group died from their arrhythmias.

Arrhythmias most often are caused by heart disease, and occur frequently in patients who have suffered previous heart attacks.

The border between dead heart tissue which was killed during the attack and healthy tissue seems to "short circuit" the normal conduction of electrical signals through the heart, causing rapid beating of the lower heart chambers, the ventricles.

Unless this rapid beating is in some way corrected, it may compromise the ability of the heart to pump blood and lead to heart failure or death.

-more-

Until recently, arrhythmias were treated primarily by implanting pacemakers in the heart, or by administering one of a battery of antiarrhythmic drugs.

However, these treatments are not effective for some patients, particularly those whose arrhythmias result from heart muscle disorders or birth defects.

One such defect, the Wolf-Parkinson-White syndrome, is characterized solely by the presence of an abnormal electrical circuit. This circuit allows the passage of extra electrical impulses which overstimulate the ventricles and cause rapid beating.

The "trick" in treating these disorders, Stinson said, is to identify where they begin. "Since we can't see them, we must detect them electrically," he said.

This is done by determining the sequence by which different parts of the heart are activated, or stimulated to beat, and zeroing in on the part that beats first.

First, the patient is brought to the catheterization laboratory, where several catheters, or small tubes with electrodes on the ends, are introduced into the heart. One catheter initiates a rapid ventricular beat, while the others "map" the activation sequence.

Next, the patient is moved to the operating room, where the chest is opened, and the circulation and breathing is taken over by machine. The empty heart is opened and the arrhythmia reinitiated.

With an electrode strapped to his finger like a ring, the surgeon performs more detailed mapping of the inside of the heart.

Once the source of the arryhthmia has been pinpointed, the surgeon cuts it away from the heart's electrical circuitry, thereby "curing" the patient.

The Stanford researchers said they would continue their studies of the mapping and surgical techniques to determine which patients benefit most from the procedure.

STANFORD—

"The incidence of sudden cardiac deaths should greatly decrease in the coming decade," a Stanford University heart specialist predicted Thursday, May 8.

"This is because doctors are making progress in being able to identify people with life-threatening arrhythmias and to treat them," said Dr. Donald C. Harrison, professor and head of the cardiology division in the School of Medicine.

Speaking at a three-day international symposium reviewing past progress in the field, Harrison added:

"If we can identify the upper 10 percent of patients who are at high risk of dying from their arrhythmias, we will have accomplished a major feat.

"This is the major challenge for medicine in the eighties."

Arrhythmias involve interference with the normal electrical conduction of the heart. They are most often caused by heart disease, and occur frequently in patients who have suffered previous heart attacks.

If left untreated, arrhythmias can lead to heart failure and sudden death.

Harrison said of the more than 1,200,000 patients who suffer acute heart attacks each year in the United States, about 120,000 fall in the high-risk category and require special treatment.

Until recently, arrhythmias were treated primarily by implanting pacemakers in the heart, or by administering one of a battery of antiarrhythmic drugs.

But doctors had to rely on trial and error to determine which drugs were effective.

If one drug did not work another would be tried, but in the meantime the patients were exposed to potentially life-threatening arrhythmias.

"Now, after a decade of progress, the mechanisms of arrhythmias and the cellular basis for them have been more clearly delineated," Harrison declared.

"In the decade of the seventies we have seen the introduction of many new antiarrhythmic drugs, and ways of determining with great certainty whether a drug is effective or not, before the patient leaves the hospital."

In addition, he said, techniques have been developed both in the catheterization laboratory and the operating room, for mapping precisely these arrhythmias in man.

He said arrhythmias which are not amenable to drug treatment could be controlled in the future with these techniques.

He said these involve methods for pinpointing the source of severe or recurring arrhythmias, and then intervening surgically to interrupt them.

"These new techniques are only beginning to gain acceptance by the medical community," he said.

Harrison said a lot of effort is now being put into research to determine which patients with arrhythmias belong to low or high risk groups.

"As our ability to identify the high-risk patient improves, we can begin to cope with the problem of sudden death in an effective way," he said.

The symposium is being held on the Stanford campus, and attended by several hundred heart specialists from the United States and abroad.

EDITORS: Photo of Lovelace available if not included with story.

STANFORD—

Her job is unusual—she tries to make the Hospital look exciting to children.

She is Betty Lovelace, the person most children meet when they enter Stanford Hospital, and a special friend to children while they're here.

As director of pediatric play therapy, Lovelace is concerned with children's constant need for diversion and stimulation through play during their hospital stay.

But she also coordinates entertaining and imaginative pre-hospital orientation and pre-operative teaching programs for young patients.

Every Sunday afternoon, through a carefully organized slide show, Lovelace introduces Stanford Hospital to young patients scheduled for admission. Slides take the children from the admission desk all the way to the trip back home, while Lovelace narrates the story with scripts appropriate for each age group.

"We try to give a feeling for the sights and sounds of the Hospital, and introduce the different people children are likely to meet," she explains. Lovelace takes care to update the slides regularly so that children recognize staff members when they actually meet.

The slides show the strange world of hospital corridors and nursing stations, hospital beds and controls, bedpans, gurneys, and all the paraphernalia required for basic tests and procedures.

"We try to anticipate and respond to the basic fears kids have like 'who takes care of me?' and 'where will I sleep?' or 'can I play?'."

Lovelace also points out aspects of hospitalization where children can exercise choice and control. These include simple things such as meals, when kids choose their own menu, or occasions such as parties, play activities and games.

"But we don't want kids to think they are coming to summer camp," she warns.

"I watch the children carefully while showing the slides, trying to stop and explain if I see a worried face," Lovelace says.

Families are encouraged to attend together and learn from the orientation. "Sometimes, family members unconsciously transmit their own fears to children," she observes.

But orientation doesn't end once the patient has been admitted, Lovelace adds. On arrival, children receive cartoon booklets. "We provide colorful little stars they can stick inside as visible rewards for mastering difficult tasks or getting through painful experiences," she says.

- more -

There is also space for autographs from new friends such as doctors, nurses and other patients.

Children are encouraged to practice their own experiences with stuffed animals. They particularly enjoy giving the animals shots or applying bandages, Lovelace says.

Handcrafted puppets and real-life dolls serve as models for demonstrating unfamiliar items including cast material, tubing, anesthesia masks and syringes.

Lovelace uses a miniature hospital for pre-surgery orientation, tracing the entire sequence of events beginning with pre-operative preparation. She describes the operating room suite, anesthetic "sleep," the recovery area, and "waking up."

The child's orientation to surgery is most successful when it is a coordinated effort of the entire pediatric team, including social workers, nurses, anesthesiologist, surgeons and play therapist, she adds.

Since children's needs differ, Lovelace has designed the programs to be flexible and individualized. One of her major interests concerns the special problems deaf and blind children face. She is adapting new approaches to help such youngsters prepare for and cope with hospitalization.

Tactile materials or aromatic substances typical of the hospital can be effective in orienting blind children, she explains.

"Recognizing the child's needs to exercise some control over the events of the day of surgery, the OR nurse may offer the sighted child a choice of color of surgery cap (instead of the the standard green). The blind child may be offered different scents on the anesthesia mask, such as oil of peppermint or cloves," she says.

Lovelace is often called upon to present her show at local schools as on ongoing health education tool for children, and she has published an article in the *Journal of the Association of Operating Room Nurses* on her work with deaf and blind pediatric patients, as well as articles in other professional journals.

Recently, the California Medical Association acknowledged the trauma children may experience on first visit to a hospital.

"The more the child understands about what's going to happen at the hospital, the less likely he will fear the visit," the CMA says. "If properly prepared, the child may even see an impending hospital stay as an 'adventure'. However, parents should not mask the more painful aspects of the experience, and risk losing the child's trust," the CMA advises.

The most convincing proof of success for Lovelace was the time one of her young patients confessed, "it's not that bad things don't happen here, but at least there are no bad surprises."

STANFORD—

The Stanford Medical Student Scholars Program has received a pledge of $25,000 annually for a period of two years from the Stanford Medical Alumni Association to support medical students in basic and clinical research projects.

"We feel this program provides an excellent scholarly experience, and financial support of the program is one of the best ways our Association has found to help medical students," said Dr. Don Goffinet, secretary-treasurer of the Association and associate professor of radiology at Stanford.

The Scholars Program, renamed the Stanford Alumni Medical Student Scholars Program following the recent gift, was established one year ago to help medical students find opportunities for creative research in clinical medicine, biomedical science or health care delivery, according to Dr. Doug Brutlag, assistant professor of biochemistry and chairman of the Scholars Program Committee.

"We're extremely grateful for the support and generosity expressed in the Alumni Association's gift," said Brutlag, "particularly since we currently have more applicants than we are able to fund."

Some medical students have been discouraged from pursuing research opportunities due to the difficulties of finding faculty sponsors, financial support and space in research groups, according to Dr. Duncan Govan, professor of surgery and chairman of the Committee on Courses and Curriculum which designed the program.

The Chase Committee in the Medical Faculty Senate has recommended that opportunities for faculty-supervised research be made available to every interested medical student, Brutlag said.

The Scholars Program provides students with academic credit for up to two quarters, 18 units of tuition remission (it costs the program $1600 per quarter per student) and a list of 112 faculty members willing to sponsor students' projects.

"We are pleased with the response from the faculty," said Brutlag. "This represents more than one fourth of the Medical School faculty, and we hope to steadily increase the number of sponsors," he added.

The Program has 16 students currently enrolled. Projects range from Edward Baer's work on purifying and characterizing the endogenous opiate, dynorphin (in Dr. Avram Goldstein's lab) to a joint project by Ami Laws and Susan Jacobson, evaluating the costs of intensive care and post-intensive care quality of life, under supervision of Dr. Myer Rosenthal, director of the Hospital's intensive care units.

Positive responses from students who have participated in the program indicate that they value highly the freedom to explore different areas of basic and clinical sciences before making career decisions, Brutlag said.

In order to receive academic credit, students are required to submit a written proposal and must later present a thesis and oral defense before the advisor and two additional faculty members.

Two alumni members will soon be appointed to the Scholars Committee, Brutlag noted, and the liaison between students and alumni may open up additional research opportunities off campus.

Through the Scholars Training Program, the Medical Scientist Training Program and the Cancer Biology Research Program, approximately half of all Stanford medical students are involved in research sometime during their medical school careers, he added.

STANFORD—

Seventy-six percent of medical students graduating from Stanford University School of Medicine this year have been matched to one of their top three choices for internship.

Fifty-four percent received their first choice and sixty-five percent will be interning in a university hopsital, according to Dr. Kenneth Vosti, associate dean for student affairs.

The match rate is the highest in the past ten years, he said.

It is the fourth year in a row that at least seventy percent of the graduates have been matched to one of their top three internship choices, he added.

Also following a pattern set in previous years, most graduates will continue their medical training in internal medicine. Pediatrics, surgery, family practice, psychiatry, radiology and pathology internships follow in popularity.

Stanford Hospital will receive the largest number of graduates, (23 out of 65) with the rest distributed among hospitals nationwide, Vosti said.

Stanford medical students' continuing high match rate is a reflection of their strong clinical performance and a counseling program that helps them apply for programs most appropriate to their level of experience and career goals, he added.

To qualify for internship programs, medical students must satisfy graduation requirements of the Medical School. These include passing parts I and II of the National Board Examinations and certain course requirements, Vosti explained.

STANFORD--

Five young volunteers at Stanford University Medical Center were awarded memorial scholarships for outstanding service by the Medical Center Auxiliary at the annual junior volunteer awards and recognition dinner held Wednesday evening, May 7.

The five junior auxiliary members, all young mid-Peninsula women, are Sheela Dave of Palo Alto, Krystyna Kaczmarek of Menlo Park, Kathleen Rice of Palo Alto, Jennifer Smart and Sheri Sobrato, both of Atherton.

Dawn McClelland, Auxiliary president, presented the scholarship awards, valued at $300 each. This is the second year the Auxiliary has sponsored the awards, which are funded by memorial donations, according to Joan Naber, junior volunteer chairwoman.

Kathleen Rice volunteered 220 hours in pediatrics, and has also been a member of the Northern Peninsula Council of Junior Volunteers for two years. She will attend Univ. of California-Berkeley next fall where she will major in petroleum and chemical engineering.

Sheela Dave has worked for 230 hours in the escort and emergency services. She is a member of the Palo Alto Medical Explorers, "S" Club and California Scholarship Federation Club at Palo Alto High School, and a member of the Junior Council of Peninsula Volunteers. Sheela plans to attend U.C. Davis next year, majoring in the biological sciences.

Jennifer Smart has volunteered 235 hours in the emergency room and on patient services, and this summer she will be employed in the Admitting Department at SUH. Next fall, Jennifer will enter Smith College to major in international relations.

Sheri Sobrato has worked 269 hours in the pediatrics service. She has been chairwoman of the Junior Volunteers in Pediatrics, and she served as the President of the Northern California Council of Junior Volunteers during the past year. Sheri has also been a volunteer for the Community Association for the Retarded and recently joined their staff. She will attend Stanford in the fall, majoring in developmental psychology with emphasis on the retarded and abnormal child.

Krystyna Kaczmarek has given 411 hours in admissions and emergency. She now works in the Hospital's Department of Dietetics while attending San Francisco State. She is a chemistry major and plans to go into nursing or medicine.

STANFORD—

Health professionals at several institutions across the country will soon take part in a Stanford University study developing and testing new methods for teaching cost-effective clinical decision-making.

The study is the first test in medical education of tutored videotape instruction (TVI), a new teaching technique developed at Stanford University.

The project is funded by a grant of $59,897 from the National Fund for Medical Education, with sponsorship from the Schering-Plough Foundation.

TVI may be valuable in medical education because it can make information available to a large number of individuals in a format that has proven teaching effectiveness, according to Dr. Harold Sox, Jr., assistant professor of medicine and chief of the division of general internal medicine at Stanford's School of Medicine.

One of the principal activities of physicians is trying to identify the causes of patients' problems with enough certainty to start specific treatment. However, most clinical diagnostic methods are imperfect, and clinicians must often take action without being perfectly certain. One goal of the project's teaching materials will be to help students deal effectively with diagnostic uncertainty, Sox said.

The health industry costs U.S. consumers about $200 bilion each year, and that figure is increasing more rapidly than general inflation, Sox explained, with diagnostic tests contributing up to 25 percent of patients' bills.

"By helping students learn how to predict when tests will be useful to them, we hope that the use of tests can be reduced without adversely affecting patients' welfare," he noted.

Another aspect to making clinical decisions is evaluating patients' attitudes toward the alternative choices, Sox said. "This is a difficult area in which to use hard and fast rules, and it has become an active field of research," he said.

Drs. Keith Marton and Edward Shortliffe of the division of general internal medicine will also collaborate on the project, scheduled to begin this summer, Sox said.

Tutored videotape instruction was developed by Dr. James Gibbons and colleagues in the School of Engineering at Stanford University, Sox noted.

Students are shown a videotape of a regular classroom session, with a tutor present. The tutor or the students may interrupt the tape at any time for discussion or clarification.

Equal performance ratings from students in taped classes and those students receiving TVI indicate that the technique is extremely effective, Sox said.

Michael Higgins, a decision analyst will assist in developing the classroom material for the TVI segments. Each tape will focus on a particular diagnostic problem, Sox explained.

The Stanford researchers are collaborating with colleagues at the Public Health Service Hospital in Seattle, the Brooke Army Medical Center in Texas, and the Dartmouth Medical School.

Those participating in tests of TVI will include medical students, graduate physicians and house staff, physicians' assistants and nurse practitioners.

The National Fund for Medical Education is a public foundation that was chartered by Congress in 1954 to mobilize voluntary support for medical education. It has awarded over $50 million to medical schools, societies and consortia since its founding. The primary mission of the Fund is to promote the best possible health care for the American public by supporting improvements in medical education.

STANFORD—

How we may inherit susceptibility to certain diseases will be the topic of the third spring Progress in Medicine lecture on May 13 at 7:30 p.m. in Fairchild Auditorium at Stanford University Medical Center.

Two experts will discuss "the hidden cost of survival of the fittest," or how the body's resistance to some diseases may be linked with susceptibility to others.

The lecture is free and open to the public.

The speakers will be Dr. Andrei Calin, assistant professor of medicine at Stanford and director of the rheumatology section at the Palo Alto Veterans Administration Medical Center, and Dr. Hugh O. McDevitt, professor of medicine in immunology and professor of medical microbiology at Stanford.

The Progress in Medicine lectures are presented as a community service by the dean and faculty of the School of Medicine, the Stanford University Hospital, and by members of the Medical Center Council.

STANFORD—

The Supreme Court's *Stanford Daily* decision has paved the way for "abusive invasions by law enforcement officials into the security and privacy of physician's offices," according to the American Medical Association and the American Psychiatric Association.

The statement was made to the U.S. Senate Judiciary Committee in reference to the decision that upheld the right of police to search the files of the Stanford student newspaper for photographs of a sit-in at Stanford University Hospital in which a crime had occurred.

The representative for both the AMA and APA, Dr. Nancy Roeske of Indianapolis, told the committee that the decision "substantially limits whatever degree of privacy was thought to have existed for innocent citizens."

Roeske said the search procedure by police, as contrasted to the subpoena request for information, "is particularly pernicious since it does not allow the physician to challenge the disclosure of his records on grounds that they're both privileged and confidential."

She further stated that the Supreme Court finding is contrary to established APA and AMA policy on the nature of patient-physician relationship and the ethics of practice.

Stanford officials had no comment about the AMA/APA position, but they said they have general concerns about the question of protecting the confidential nature of doctor-patient relationships.

They recalled a case in 1973 in which two investigators from the Santa Clara County District Attorney's Office, using a search warrant to gain entry, attempted to search the medical record files of the Stanford University psychiatric clinic, seeking evidence in the prosecution of an alleged sex offense case.

Medical School officials at the time surrendered the youth's file while telling the investigators they could not go through the psychiatric files because of the confidentiality of the names of other patients.

The investigators complied and did not conduct a full search.

The AMA and APA support legislation by Senators Birch Bayh (D-Ind.) and Max Baucus (D-Mont.) protecting innocent third-party records held in privileged relationships or those protected by First Amendment rights from illegal search and seizure.

The statement outlining the AMA and APA positions on this issue is scheduled to appear in the May 9 issue of the *Journal of the American Medical Association.*

STANFORD—

A Stanford University official Tuesday said there is no impasse in the talks between Stanford and community physicians, and expressed confidence the two groups have clearly laid the basis for future agreement.

Robert Rosenzweig, vice president for public affairs, made the statement in a letter to Palo Alto Mayor Alan Henderson. Both the mayor and community physicians recently wrote letters expressing doubts in the outcome of the current discussions.

The talks center on whether community doctors should be given access to certain hospital services now restricted to full time faculty.

"My own view is that there has been a good deal more progress on that matter than either the Council's letter or the recent letter from the Community Physicians for Patient Care suggest," Rosenzweig declared.

A joint Stanford-Palo Alto physicians' liaison committee last month proposed a plan to give community doctors controlled access to the Hospital's special facilities and laboratories. As community doctors with staff privileges in the designated services leave or retire, they would be replaced by community doctors who hold clinical faculty appointments in the Medical School.

Rosenzweig said the proposal "clearly contains a mutually acceptable approach to the questions of future access.

"It is easy to deprecate the progress that has been made because there is still a good deal of heat associated with the details of implementing the approach. But the basis for the agreement is there and that is the most important fact of all."

Henderson informed Stanford officials two weeks ago that the city council was dissatisfied with the progress of the discussions.

The mayor said the council had asked the city attorney to meet with Stanford officials to determine if the University was complying with the provisions of the city contract.

-more-

The contract in question was signed in 1968 as part of an agreement under which Palo Alto sold its interest in the Hospital to the University. In exchange Stanford guaranteed priority in a large block of beds to patients from the community and assured local physicians of staff rights.

However, future appointments in certain hospital services were to be restricted to full time faculty. These services include anesthesia, cardiology, neurology, pathology, radiology as well as other specialized laboratories.

In 1978 the board of hospital directors reaffirmed this policy. Private physicians formed the Community Physicians for Patient Care to fight the decision. In response the Stanford-Palo Alto physicians' liaison committee was formed to grapple with the problem.

Indicating that discussions between the respective attorneys over the contract issue have begun, Rosenzweig added, "I am confident they will serve to reassure citizens and council members that Stanford has been faithful in meeting the obligations it undertook in 1968."

Rosenzweig said the resolution of the hospital-based services issue seems to be reasonably simple compared to the really important and difficult questions facing the Medical Center in the future.

"Those problems will arise from the conflict between a fixed set of obligations for community care and rapidly changing conditions affecting medical education," he said.

He included biomedical research, technology, the delivery and payment of medical services, and the problems of the University of which the Hospital and Medical Center are part.

"These are formidable issues," he said, "and the way they work themselves out will affect the quality of medical care available in this area and the conditions of medical practice.

"Until now no one has been much disposed of to look far enough ahead to begin to grapple with the future. For different reasons the University, the local medical profession and political leaders have been absorbed in much shorter range preoccupations.

"If we continue to act as though the conditions of the past decade will obtain in the future, I am afraid we will have trouble—University and community alike—that will dwarf our present difficulties. I hope very much that we will not lose the chance to discuss these longer range issues."

STANFORD—

Gary Mecklenburg, administrator of Stanford University Hospital and Clinics, will leave his post September 1 to become president and chief executive officer of St. Joseph's Hospital in Milwaukee, Wisconsin.

Mecklenburg, 34, will also become a member of the board of directors of St. Joseph's Hospital, a 570-bed community and teaching hospital affiliated with the Medical College of Wisconsin and Marquette University.

Stanford Hospital Executive Director Dr. Peter J. Levin expressed his regrets at Mecklenburg's departure, citing his "strong administrative leadership which has made the Hospital much more responsive tp patients' needs."

Among Mecklenburg's accomplishments, Levin pointed to improvements in the Hospital's budgeting process, employee relations, and operating procedures.

"Gary's leadership in control of expenditures resulted in the slowing down of the rate of increase at a time of unprecedented national inflation," Levin said.

The annual rate of increase has been cut from an average of 19.1 percent during trhe years 1973 to 1977, to less than nine percent in the past three years, "significant savings" beyond the national average, he said.

Mecklenburg was appointed administrator of Stanford University Hospital and Clinics in 1977. Prior to that he was deputy director. He has also been a lecturer at Stanford in the department of family, community and preventive medicine since 1978.

Before coming to Stanford Hospital in 1977, Mecklenburg was associated with the University of Wisconsin Hospitals in Madison from 1970 to 1977 as assistant superintendent and later associate superintendent.

He received his B.A. degree in anthropology from Northwestern University in 1968 and his M.B.A. degree in hospital administration from the University of Chicago in 1970.

Mecklenburg received the Harold M. Coon, M.D. Award of Merit of the Wisconsin Hospital Association in 1974, naming him Wisconsin's Young Administrator of the Year.

He is a member of the American College of Hospital Administrators, a member of the executive committee of the Hospital Conference of Santa Clara County, and a member of the Board of Directors of Northern California Central Services, Inc.

STANFORD—

Dr. Louis Krasno plans to retire from the practice of medicine this year, so he can concentrate on another career—playing the gypsy violin.

Krasno, a clinical assistant professor at Stanford University School of Medicine, is leader of the Gypsy Trio, which performs for benefits and social functions on the Peninsula.

Over the past 17 years, the Trio has played before such notables as the late President Dwight D. Eisenhower, former President Gerald Ford, the late Maurice Chevalier, Victor Borge and Helen Hayes.

Dressed in colorful vests and sashes tied about the waist, the three musicians played recently at the Lytton Gardens retirement home in Palo Alto.

Their music is moody, yet stirring. It suggests an earlier, more romantic age, which celebrated life with gusto.

"We're trying to preserve this type of music—gypsy music—that has all but disappeared in this country," says Krasno.

Krasno was born and grew up in the Austin area of Chicago, and learned to play the violin when he was only five years old.

His mother and father, emigrants from Hungary and Romania respectively, taught him to play by ear, "like the gypsies," he says.

He earned a Ph.D. in physiology and his M.D. from Northwestern University in 1944, and afterwards set up practice in Evanston, Illinois, specializing in cardiology. Later he served as a medical officer in the Navy, and as a consulting cardiologist for United Airlines, a position which he still holds.

In 1957, he moved to the Bay Area. He has been a member of the clinical faculty at Stanford for the past 15 years, helping train medical students and residents, and doing research in the area of heart disease prevention.

But he has never lost his love of music, and today feels even more strongly about the need to keep the musical legacy of the gypsy culture alive.

"In New York City 20 or 30 years ago, there were dozens of gypsy cafes where we'd play all night," he recalls. "They are all closed down now.

"You can still find gypsy musicians in Europe, but in the U.S. they are virtually extinct. For some reason, the musician is no longer a part of gypsy society here."

Krasno's partners in the trio are Carlos Velez, of SRI, International, who plays the guitar, and Albert Norris, who is in the oil exploration business and plays bass. Both formerly were professional musicians schooled in jazz.

"When I was looking for partners for a trio in the early 1960s, I found that jazz musicians were far more flexible than classical musicians," Krasno says.

"Jazz relies on improvisation which is essential to gypsy music."

Today, the Trio performs in retirement homes, before audiences who "can't get out to hear this kind of music," Krasno says.

"We're trying to excite interest in gypsy music," he added. We've made some recordings, so even if no one follows in our footsteps, at least we will leave the music behind us."

STANFORD—

A three-part curriculum in basic medical science, clinical medicine and investigative medicine has been approved in principle by the faculty senate of the Stanford University School of Medicine.

The action should serve to notify prospective students, faculty and other interested parties "that Stanford expects its graduates as well as its faculty to play a major role in the advancement of medical knowledge, and that it expects to be a leader in the development of academic physicians," according to a statement by the committee of five, the executive board of the senate.

The curriculum already requires that students demonstrate competence in the basic sciences and clinical medicine before graduation.

The addition of the third requirement, investigative medicine, "embodies what is special about the School and its avowed mission to train all our students for leadership in the practice of scientific medicine," said Dr. Avram Goldstein, senate chairman and professor of pharmacology.

The committee of five is expected to appoint an ad hoc committee on investigative medicine in the next few weeks, to study the feasibility of the plan, and determine specific proposals and a time-table for phasing them in.

According to the statement by the committee of five, "Stanford Medical School currently has an elective curriculum, wherein medical students have a great deal of flexibility in deciding how they shall achieve the requisite knowledge to develop competence in the basic and clinical medical sciences.

"The task before the ad hoc committee on investigative medicine is to develop curricular and research opportunities under a third part of the medical curriculum without compromising either the basic elements of the present curriculum or the dictum to produce outstanding clinicians and practitioners of scientific medicine."

Basic elements of the Medical School curriculum are electivity of course work, pass-fail grading, and program flexibility.

Senate member Dr. Irving Weissman said that under the proposal, investigative medicine would be taught in a "two-arm" approach—through course work on research methodology, experimental design and interpretation, and through a "hands on" science project.

-more -

Investigative projects would not be limited to bench research, but could include clinical studies, research on epidemiology, health policy, or preventive, community and public health. The projects could be based entirely on library research, or could involve research in various University departments outside the Medical School.

Through the three-part curriculum, "graduates of this medical school would have the option of pursuing either clinical or academic medicine through postgraduate training," said Weissman, an associate professor of pathology.

The curriculum evaluation committee of the faculty senate, chaired by Professor Byron W. Brown, of the Department of Family, Community and Preventive Medicine, estimated that the proposed program might cost $250,000 a year, "and will rise with other costs."

The committee said it would be possible to "raise this amount of money for this educational experiment, a unique program of training in investigative medicine."

A major impetus for approval of the three-part curriculum is the need to train more minority students for careers in academic medicine.

Citing the School's dismal record in attracting qualified minority faculty, Goldstein said Stanford has an obligation to try to identify and attract the kind of minority students who are committed to academic careers in order to help alleviate the shortage of minority faculty members in medical schools.

Goldstein said that minority faculty development is an area in which Stanford with its unique resources can make its greatest contribution.

News Bureau Stanford, California 94305

VACANCY ANNOUNCEMENT

POSITION: SCIENTIFIC WRITER III

DEPARTMENT: MEDICAL CENTER NEWS BUREAU

DURATION: Permanent, Full Time

SALARY: $1485-1919 per month, depending on experience

DUTIES:

The News Bureau of the Stanford University Medical Center is seeking an experienced science writer to report and write articles covering a wide range of the clinical and basic medical sciences, and the programs of a University Hospital, including short news items as well as longer features.

This individual will also have the following duties:

— Write and edit a monthly publication for the hospital medical staff.

— Work as the associate editor of the *Stanford M.D.* magazine, contributing original articles, preparing the general and science news section, class notes, and working with designer on layout and production aspects.

— Act as liaison to news media seeking information about Medical Center activities and respond to inquiries from reporters and editors.

— Contribute news stories to Campus Report/Medical Center Memo supplement on a weekly basis.

— Serve on editorial committees.

QUALIFICATIONS:

A minimum of 3 years of writing and editing experience is required, with general knowledge of medical sciences and biology. Candidates with a combination of journalistic experience and with a portfolio demonstrating clearly they can write for both scientific and lay audiences will be given preference. Similarly, journalistic experience and prior work with an academic medical center information office will be given consideration. Creative ability, interviewing skills, and a general understanding of medical and scientific terms with attention to detail and accuracy are important. Some experience in working with designers on layout and production is also required.

APPLICATION PROCESS:

Qualified candidates should submit a detailed resume, including salary requirements, and provide representative samples of published material by July 15, 1980 to:

Linda Stabler
Personnel Department-VAC
Serra and Galvez Streets
Stanford University
Stanford, California 94305

STANFORD—

During the summer months when students and faculty are away and many hospital employees are on vacation, the Stanford University Blood Bank (SUBB) must turn to the community to meet its blood needs.

This summer SUBB will be setting up mobiles at many businesses in the area, including Macy's, The Emporium, Lockheed and Hewlett-Packard.

Summer is traditionally a slow time for blood banks around the country and this is also true at SUBB since students and faculty at Stanford are such generous donors.

In the past nine months, students alone donated 2500 productive units of blood, which is roughly 20 percent of the total blood given since SUBB began in March of 1978. A productive unit is one that can be transfused.

"Students have less ambivalence about this kind of giving," says Ellen Fox, hospital coordinator for SUBB. "It appeals to them." Flexible schedules and active recruiting at campus dorms also help, she said.

Although most community hospitals need only 5000-6000 units of blood a year, Stanford uses 30,000 units a year to meet the needs of the cardiovascular unit, leukemia and other blood diseases, premature nursery and patients at Children's Hospital at Stanford.

A single blood donation can help as many as four patients since blood can be separated into component parts such as platelets, red cells and plasma.

Anyone age 18 to 65 can donate blood as often as five times a year. A child of 17, however, can give blood with parental permission and those 65 years and older can do so with a physician's approval.

SUBB offers a credit policy for each pint of blood donated. Credits are cumulative and may be assigned at any time to any patient at Stanford University Hospital or to an immediate family member. A credit erases the replacement fee that some blood carries for a period of one year following each donation.

These credits also can be used for immediate family members in other hospitals throughout the country, according to guidelines set up by the SUBB.

Giving blood takes only five to seven minutes, although donors should allow at least 45 minutes for the donating process, which includes registration, a brief medical history and a 15-minute rest period afterwards.

"In no way does giving blood impede a person's normal functions," says Mary Ward, campus coordinator for SUBB and a regular donor. "We tell them (donors) not to do any strenous activity. . . otherwise there are no restrictions."

STANFORD—

A life support training center for local citizens and health care professionals has just been opened by Stanford University Hospital.

Dedication ceremonies for the center, which will offer both basic cardiopulmonary resuscitation (CPR) and advanced cardiac life support (ACLS) techniques, were held on June 19.

The new facility which is located next to the Hospital's Emergency Department, cost $20,000 to construct and was funded largely through donations from local service clubs and businesses.

Todd Kiskaddon, a certified paramedic in Santa Clara County, who is trained in both CPR and ACLS, has been hired by the Hospital as the center's coordinator.

On the peninsula, the American Red Cross and the American Heart Association have a long history of providing life support training techniques. The Hospital will make the center and its equipment available to these organizations to expand their activities.

In addition, members of local service clubs will be trained as instructors and they, in turn, will be able to train their own people at the center.

"Our goal," says Dr. Michael Eliastam, emergency services director, "is to saturate the area with people trained in CPR."

CPR training teaches the ability to provide life-sustaining care until an ambulance arrives on the scene, or a victim can be transported by some other means to an emergency department.

ACLS training, however, goes beyond the capabilities of lay persons and involves the use of drugs, intravenous lines, electrocardiogram and breathing assistance machines, as well as defibrillators.

Certification in ACLS will be required of all physician and nursing personnel in the Hospital's emergency department.

Both programs will be offered at the center on an informal as well as a formal basis. Self-teaching modules and individual performance testing will be available and the center will be open in the evening as well as during the day.

"Because a lot of physicians don't deal with emergency situations very often," says Eliastam, "this will give them the benefit of honing their skills on their own time. . . without close scrutiny."

Operation of the center will cost the Hospital $50,000 a year. This figure includes the coordinator's salary, secretarial support and funds for an equipment technician.

Donors to the construction and equipment of the facility include Raychem Corp., Menlo Park; the Rotary Clubs of Palo Alto and Menlo Park; the Kiwanis Clubs of Palo Alto and Menlo Park; Palo Alto Host Lions and South Palo Alto Lions; Aldo J. Test, an attorney.

Along with Eliastam, Dr. Kent J. Garman, associate professor of clinical anesthesia, and Barbara Behrens, clinical nurse coordinator in emergency, have been the most active proponents of the center.

STANFORD—

The organization representing most of the registered nurses at Stanford University Hospital today gave notice of its intention to strike if a new collective bargaining agreement is not reached by midnight, July 4, 1980.

The Committee for the Recognition of Nursing Achievements (CRONA), which represents over 1,000 of the Hospital's non-supervisory staff registered nurses, has been negotiating with the Hospital on the terms of a new agreement since May 20.

The current agreement will expire June 30. Under the National Labor Relations Act, CRONA is required to give 10-day notice of its intention to strike.

Joanna Nelson, R.N., chief negotiator for CRONA, said, "We have one goal in mind—reaching an agreement."

Even in the event of a strike, "We will make sure patient care is not compromised." That includes providing coverage of critical care and other areas from which patients cannot be moved to other hospitals, she said.

Hospital administrators are meeting this week to make contingency plans for the possible strike.

The plans may include closing selected units, limiting admissions to nonelective and emergency cases, and making provisions for transfering patients to other hospitals, according to a schedule which depends on the progress of the negotiations, said Hospital Administrator Gary Mecklenburg.

Priscilla Wheeler, chief negotiator for the Hospital from the University Counsel's Office, said, "The Hospital desires to reach a mutually acceptable agreement as soon as possible."

She said the negotiators are working to resolve "a number of outstanding issues," but neither side would give details today.

Wheeler added that a federal mediator may join the negotiations, but so far the Hospital has not been contacted by the Federal Mediation and Conciliation Services, which provides mediators to help resolve labor disputes once a strike notice has been filed.

STANFORD—

Stanford University School of Medicine will maintain a "full program" of residency training in surgery at Santa Clara Valley Medical Center next year, despite the resignation of five of its faculty members.

According to Dr. Lawrence G. Crowley, acting dean of the Medical School, three of the five positions have been filled, and active recruitment is underway to fill the remaining two.

Dr. David Burton, associate professor of clinical surgery, has been appointed chief of orthopedic surgery at Valley.

Dr. Dennis Becker, chief resident in neurosurgery, has been named chief of neurosurgery at Valley, and a clinical assistant professor of surgery at the Medical School.

A third vacancy, in orthopedic surgery, will be filled by four physicians from the San Jose Orthopedic Medical Group, who probably will rotate as clinical faculty on a monthly basis, according to Burton.

They are Drs. Mark Golod, John Stahler, John Dedinsky, and Paul Swartz.

The new appointments become effective the same day as do the resignations, July 1.

Valley Medical Center has had a long-standing affiliation agreement with Stanford.

According to the agreement, the Medical School provides staff for various services at Valley, including surgery, medicine, gynecology and obstetrics, dermatology, psychiatry and neurology as part of the teaching program of house staff and medical students.

However, the programs in orthopedic surgery and neurosurgery were cast in doubt last February, when five Stanford faculty members with appointments in the department of surgery at Valley submitted resignations.

They included all three orthopedic surgeons, Drs. Clyde Alan Farris, Steven S. Fountain and John Harding, and the only neurosurgeon, Dr. Richard D. Hamilton.

In addition, Dr. A. Crane Charters, chairman of the surgery department, resigned.

According to Robert Sillen, executive director of Valley Medical Center, the surgeons resigned for a "full spectrum of reasons," some of them personal. For some of the doctors, an important reason was failure of Stanford and the County to reach an agreement on a practice plan proposed by the medical staff last September.

-more-

The plan would have converted the present system of paying faculty strict, full-time salaries, to an incentive situation, under which faculty members would keep some of the professional fees they earned to support their salaries, as well as their individual teaching and research activities, Sillen explained.

"In my opinion, the practice plan concept is in the best long-term interest of the medical staff and Valley," he said.

However, "it is not at all clear" what such a plan would have done to the relationships between the County, Stanford, and the physicians themselves.

"One issue for Stanford is, how does the University retain enough control over the academic process, including faculty appointments and salary levels, when it is run by a private group?" Sillen said. "That is a valid concern."

In addition to the resignations, some officials at Stanford had become concerned about the future of Valley. Extensive renovation of the physical facilities are required, yet the potential passage of Proposition 9 raised the specter of reduced funds to state-aided institutions like Valley.

Accordingly, groups were formed both at Valley and at Stanford to review the affiliation agreement and discuss the long-term goals and needs of both institutions.

"Now that Proposition 9 has been defeated, we can begin more definite long-range planning to strengthen and reaffirm the relationship between the Medical School and Valley Medical Center," said Crowley.

"Stanford has little to worry about as far as the future viability of Valley is concerned," Sillen added. "Valley has a bright future. We're going to be here a long time."

STANFORD—

Five members of the Stanford University School of Medicine faculty have been promoted to tenured positions, effective September 1, 1980, the Dean's office has announced.

They are Drs. Douglas L. Brutlag, Allen D. Cooper, Leslie J. Dorfman, Michael F. Marmor, and I. Ross McDougall.

Brutlag, associate professor of biochemistry, is noted for his studies of the molecular structure of chromosomes, and has succeeded in making chromosomes from their component parts, DNA and proteins.

The work is providing a better understanding of the structure of chromosomes and of the way new ones are put together when cells divide.

Brutlag, 34, earned his bachelor's degree at the California Institute of Technology in 1968, and his Ph.D. at Stanford in 1972. He served as a research scientist with the Commonwealth Scientific and Industrial Research Organization before joining the Stanford faculty in 1974.

He is founder and first chairman of the Stanford Medical Student Scholars Program, and recently was awarded a Camille and Henry Dreyfuss Teacher-Scholar Grant.

Cooper, associate professor of medicine, is well known for his research on the factors that regulate the body's synthesis of cholesterol.

A native of New York City, Cooper received his M.D. from the State University of New York in 1967.

He served as resident and research fellow at University of California Medical School in San Francisco, and as staff gastroenterologist at the Wilford Hall United States Air Force Medical Center in San Antonio, Texas before coming to Stanford in 1974.

His honors include invitations to participate in the Deuel and Gordon Research Conferences, a National Institutes of Health research career development award, and membership to the American Society for Clinical Investigation.

Cooper also plays an active role in teaching and clinical care, serving as coordinator of the gastroenterology section of the physiology course, director of the Clinical Gastroenterology Laboratory, and as chairman of the Department of Medicine's committee on quality assurance.

Dorfman, associate professor of neurology, is known as an innovator in the assessment of nerve disorders.

He introduced a new method for indirectly measuring the velocities at which electrical impulses are conducted along the spinal cord, and demonstrated that this velocity is slowed in the elderly and in patients with multiple sclerosis. The measurement is particularly useful in detecting small spinal cord lesions.

more-

In addition, Dorfman has developed a method of determining the speed with which different sizes of nerve fibers conduct impulses. This technique may aid doctors in identifying the effects of different forms of peripheral nerve damage, that which occurs in nerves outside the brain and spinal cord.

A native of Montreal, Canada, Dorfman received his M.D. at Albert Einstein College of Medicine in New York in 1968.

He served as resident and as acting instructor in neurology at Stanford before being appointed assistant professor in 1974.

He founded and directs the Evoked Potentials Laboratory, and also directs the Electromyography Laboratory. Electromyography refers to recordings of the electrical potential of nerve and muscle, an essential technique in diagnosing neurological disorders.

Marmor, associate professor of surgery (ophthalmology), is considered one of the few leaders in the field of electroretinography.

Electroretinography is the measurement of changes in electrical potential in the retina after stimulation by light, and is used to evaluate visual function.

In addition Marmor is well known for his studies of retinitis pigmentosa, one of the most common dystrophic diseases of the retina, and of the adhesive forces which hold the retina in place. The latter study may lead to better treatment of detached retinas, a common cause of visual impairment and blindness.

Marmor received his M.D. at Harvard Medical School in 1966. He served as assistant professor of ophthalmology and director of the Clinical Electrophysiology Unit at the University of California Medical School in San Francisco before coming to Stanford in 1974.

In addition to his research, Marmor directs the Stanford Clinical Electrophysiology Unit, and teaches in undergraduate courses in electrical engineering and human biology, as well as in medical school classes and postgraduate medical education programs.He also serves as chife of the Ophthalmology Section at the Palo Alto Veterans Administration Medical Center.

McDougall, associate professor of radiology and medicine, has been studying the use of radioactive substances in improving diagnosis and treatment of a variety of diseases.

For example, he developed a sensitive and highly specific method for detecting abscesses throughout the body, by white blood cell scanning. A major interest has been the use of radioisotopes in the diagnosis and treatment of thyroid disease.

In addition, he has been studying vesicles, tiny cells which can be made in the laboratory from fatty materials. Vesicles have proved useful in understanding the mechanisms of disorders such as Graves ophthalmopathy, and they may also be used in the future to carry drugs to specific areas of the body.

A native of Scotland, McDougall received his medical degree in 1967, and his Ph.D. in 1973 from the University of Glasgow.

He served as lecturer in medicine at the University Department of Medicine, Glasgow Royal Infirmary, before coming to Stanford in 1976.

STANFORD—

Early detection of diabetes, rigorous control of blood sugar, and continuous surveillance of fetal well-being are essential for reducing death and disease among infants born to diabetic mothers, according to a University of Pennsylvania fetal medicine specialist.

"The majority of women have had little nutritional education when they become pregnant," and diabetes may go undetected until their first check-up, said Dr. Steven G. Gabbe, director of the fetal medicine division at the University of Pennsylvania in Philadelphia.

While this may not be a problem for most mothers and babies, chronic, uncontrolled diabetes during the first trimester of pregnancy increases the risk of life-threatening birth defects two to three fold, he said.

Death from birth defects of the heart, skeleton, central nervous system and kidneys today kills more babies of diabetic mothers than any other cause.

The overall perinatal death rate associated with diabetes has been cut from about 30 percent in the 1940s to only five or six percent today, mostly due to advances in fetal monitoring and increased use of cesarean section delivery, Gabbe said.

However, complications of excessive birth weight, low blood sugar, and prematurity continue to plague the babies, and indicate a need for improved understanding and control of the disease.

Gabbe spoke on the problems of diabetes in pregnancy on Monday, June 16, during a three day conference on the nutritional care of high-risk mothers and infants at Stanford University School of Medicine.

The conference, for nutritionists, nurses and physicians involved in obstetrics and neonatology, is being held in the Medical School's Fairchild Auditorium, and is sponsored by the Department of Pediatrics under a grant by the Department of Health, Education and Welfare.

Gabbe recommended that "every pregnant patient should be screened for diabetes," at least by measuring her blood sugar one hour after she has been given a 50 gram dose of glucose (sugar).

If diabetes is detected, and if insulin is required, nutritional therapy should also be instituted, he said.

"Diet rarely gets attention," Gabbe said, yet it is important to balance the daily dosage of insulin with the diet as well as physical activity and stress in order to prevent large shifts in blood sugar levels during the 24 hour period.

In addition, the patient should be taught home glucose monitoring—how to test her blood for higher than normal blood sugar levels throughout the day.

more-

Home monitoring "keeps the patient out of the hospital and gives her much more control over her diabetes," Gabbe said.

The nutritional needs of premature infants were explored during Monday morning's session by Dr. Norman Kretchmer, director of the National Institute of Child Health and Human Development in Bethesda, MD.

Kretchmer said in 1960 not a single baby in New York born between 750 and 1,000 grams survived. According to statistics from Stanford's nurseries, today the survival rate among such babies is 80 to 90 percent.

"The reason we have been able to deal with these immature infants is that we have learned how to feed them," Kretchmer said.

"The premature infant is an organism that has not been 'baked' in the oven long enough," he said. "Therefore, it has no ability to utilize the protein in the diet in terms of making amino acids essential for development."

The biomedical capabilities of the premature infant are indeed limited, he added. "The less fat they are the more difficulty they have in adjusting to temperature. This problem has led to the development of isolettes to care for them."

Kretchmer said advances of the last 20 years are changing "our concepts of pregnancy, and prematurity in terms of daily nutritional requirements.

"Preemies require much more protein than any adult can tolerate," he said.

In fact, the amount of daily intake of protein required by premature infants is equivalent to an adult eating three pounds of meat per day.

Kretchmer concluded that the U.S. is entering into an era of "nutritional individuality" in which mothers, babies and other adults can be accommodated in terms of their individual nutritional requirements.

STANFORD—

A $4 million project for renovation of the outpatient clinics in the Medical Center's Boswell building was approved by the University Board of Trustees Friday, June 13.

The renovation project, funded in part by a $3 million gift from the James G. Boswell Foundation, will be the first significant upgrading of the clinic facilities since their construction in 1959, according to David Mendelow, associate dean and administrator of the clinics.

The Boswell Foundation, located in Los Angeles, supports hospitals and other health care facilities and community organizations in California and Arizona.

The clinic remodeling project will complement a proposed $97 million program to correct deficiencies and modernize the Hospital over the next six years.

Both the Hospital and outpatient clinics are housed in the large Medical Center complex built in 1959 and designed by architect Edward Durrell Stone. The clinics are located in the Boswell building which comprises one wing of the complex.

In the clinics, faculty physicians treat their patients and teach medical students. The clinics receive more than 130,000 patient visits annually.

However, "the clinics were never designed to meet the needs of modern medical practice," a recent planning report noted. "They have inadequate waiting areas, undersized examining rooms, and major impediments to the attraction of patients and the integration of patient care and teaching activities."

Planned improvements include increasing the size of examining rooms; increasing conference teaching space; streamlining corridor and hallway patterns; consolidation of special procedure rooms; construction of more private interior waiting areas; and general brightening and refurbishing to improve the clinics' appearance and comfort.

"The completed facility will be more conducive to teaching," noted Mendelow. "It will also be more pleasant for patients, allow for more privacy, decongest traffic in the hallways, and permit greater efficiency through grouping of similar activities."

The architectural firm of Almeter and Finley in Palo Alto has been selected to do the design.

Once design plans are submitted, final approval for construction to begin will be sought from the University trustees in early 1981, Mendelow said.

A completion date has not been forecast, he noted, but during renovation, the clinics will remain open to patients.

Stanford University School of Medicine presented 140 degrees during its annual commencement exercises Sunday, June 15.

The ceremonies also honored seven Medical School faculty members for outstanding achievements in teaching.

Medical degrees were presented to 78 men and women. The Medical School also awarded 25 Ph.D.'s, 30 master's degrees (including 27 in physical therapy), and seven bachelor's degrees in medical microbiology and basic medical sciences.

The diplomas were presented during ceremonies in Stanford Medical School's Grant Courtyard following the University's 89th annual commencement at Frost Memorial Amphitheater.

Dr. Norman Blank, professor of radiology, was selected by the medical graduates to receive the Arthur L. Bloomfield Award for excellence in the teaching of clinical medicine.

Blank was also voted the Henry J. Kaiser Award for excellence in clinical teaching, the fifth time he has received the award in the 18 years he has been a member of the Medical School faculty.

The other Kaiser Award for excellence in clinical teaching was given to Dr. Thomas Raffin, acting assistant professor of medicine.

Drs. Thomas Mathers and Peter Sargent, assistant professors of structural biology, were voted Kaiser Awards for excellence in preclinical teaching.

The Henry J. Kaiser Family Foundation Award for outstanding and innovative contributions to medical education was shared by Drs. Robert Chase, Emile Holman Professor of Surgery, and Duncan Govan, professor of surgery.

Both had received the award previously; Chase in 1978 and Govan in 1977.

Sarah Semans, associate professor emeritus of physical therapy, received the annual Lucille Daniels Recognition Award for outstanding contributions to physical therapy.

Semans, who retired from full-time teaching in 1969, has remained active in the Division of Physical Therapy, and in clnical activities.

The Medical School commencement address was delivered by Dr. Robert J. Glaser, former dean of the Medical School from 1965 to 1970, who currently is president of the Henry J. Kaiser Family Foundation.

Diplomas were presented by Dr. Lawrence G. Crowley, acting vice-president and dean of the Medical School. He was assisted by Govan and Terry Sanford, lecturer in physical therapy.

STANFORD—

Three eminent professors in the Stanford University School of Medicine have been named to endowed chairs by the University Board of Trustees.

They are Dr. I. Robert Lehman, the William M. Hume Professor in the School of Medicine; Dr. Hugh O. McDevitt, the Joseph D. Grant Professor in the School of Medicine; and Dr. Philip Sunshine, the Harold K. Faber Professor in Pediatrics.

Lehman, a biochemist, has made important discoveries that help explain how the genetic substance, deoxyribonucleic acid (DNA), is replicated during cell division, how it is repaired following damage by radiation and toxic chemicals, and how it recombines during the exchange of hereditary materials between cells.

Recombination permits an organism to try out a number of arrangements of its genes in search of those that give it optimal selective advantage. It is regarded as a major driving force in evolution.

The Hume chair was established in honor of the late William Mansur Hume of Woodside and San Francisco. A native of Indiana, Mr. Hume was the founder of Basic Vegetable Products, Inc.. He had served as president, chairman and director of the San Francisco-based firm until his retirement in 1974.

In his will, Mr. Hume left Stanford School of Medicine approximately $5.6 million to be used for "basic research in medicine." A portion of the funds was set aside to establish the chair whose holder must meet that requirement.

McDevitt, holder of the Grant chair, is engaged in research on the genetic control of the immune system. His discoveries include a little known protein molecule called the human leukocyte antigen (HLA) which helps explain why some people may be susceptible to disorders ranging from arthritis to certain forms of cancer.

The Grant chair was established in 1969 to honor Joseph D. Grant, a leading California industrialist, financier and merchant and a member of the University Board of Trustees for 51 years. The first chair holder was Nobel Laureate Joshua Lederberg who left Stanford two years ago to become president of Rockefeller University.

Sunshine, the Faber Professor, is a specialist in neonatal medicine and pediatric gastroenterology. His research has been concerned with the study of the physiologic and biomedical handicaps of the prematurely born infant. Sunshine has been largely responsible for the establishment of the nationally recognized Clinical Research Center for Premature Infants at Stanford.

The Faber chair, whose first holder was Dr. Norman Kretchmer, former chairman of pediatrics and now director of the National Institute of Child Health and Development in Bethesda, Maryland, honors the late Dr. Harold K. Faber, an internationally known Stanford professor and founder of Children's Hospital at Stanford.

EDITORS: There will be a brief photo opportunity with Kennedy and others at 5 p.m. or later today, following adjournment of the Board of Trustees meeting at Stauffer Auditorium. This is adjacent to Hoover Tower, between the Lou Henry Hoover Building and the Herbert Hoover Federal Memorial. Please note the trustee meeting may go as late as 6:30 p.m. because of its lengthy agenda. Kennedy plans a press conference at 9 a.m. Tuesday, June 17, at the President's Office Building on Inner Quad. He will be engaged in commencement activities and previously planned travel off campus until then.

FOR IMMEDIATE RELEASE

STANFORD—

Stanford Provost Donald Kennedy, commissioner of the Food and Drug Administration during 1977-79, will become eighth president of the University Aug. 1.

A Stanford faculty member since 1960, Kennedy will succeed Richard W. Lyman, who will become president of the Rockefeller Foundation on the same date.

Kennedy's selection was announced Friday, June 13, by Dr. Peter Bing, of Los Angeles, president of the Board of Trustees, following a thorough national search. Kennedy was the unanimous first choice of trustees, faculty, students, and alumni who participated in the search.

Lyman said: "Having known Donald Kennedy virtually since his arrival at Stanford 20 years ago, I am most enthusiastic that the trustees have asked him to be the University's next president.

"He brings to the office many strong qualities: flair, imagination, a quick and agile mind, and a great capacity to bring out the best in other people. We couldn't be in better hands."

Kennedy said that "under Presidents Wally Sterling and Dick Lyman, Stanford has moved into a preeminent position among America's private universities. It is a privilege as well as a challenge to succeed to this tradition."

Kennedy, 48, has long been highly regarded as a teacher, scholar, and administrator. During the past decade, he has been considered for the presidency at Harvard, Chicago, Cornell, and Yale.

As Stanford's top academic officer, Kennedy will be concerned with more than 11,700 students, about 7,000 faculty and staff, and a consolidated budget of $487 million annually.

A biologist, Kennedy is a member of the National Academy of Science and the National Institute of Medicine. He is a fellow of the American Academy of Arts and Sciences and of the American Association for the Advancement of Science.

Born Aug. 18, 1931, in New York City, Kennedy holds three degrees from Harvard—A.B., 1952; A.M. 1954; and Ph.D., 1956, all in biology. A former ski racer and coach at Harvard, he weighs 165 and stands six feet, one inch—"high enough to hit the volleyball down, but not inside the spike line," he once observed.

While at the FDA, he and his wife, Jeanne, now community relations director at Stanford Hospital, were named honorary national cochairmen of the Committee for the Stanford Griffins, a new mascot proposed by Stanford athletes.

The Kennedys celebrated their 27th wedding anniversary Wednesday, June 11. They have two daughters, Page, a Hampshire College graduate now in South America and Julia, a Stanford sophomore.

Kennedy is the first athletic coach to become head of Stanford since Sterling in 1949 and the first biologist since David Starr Jordan, the University's first president, in 1891.

Besides volleyball, his recreational interests include skiing, trout fishing, and running.

* * *

In the mid-1960s, he was named to the first Committee on Undergraduate Education at Stanford by President Sterling, now the University's chancellor. Kennedy received Stanford's top honor for undergraduate education, the Dinkelspiel award, in 1976.

Graduating seniors have asked him to speak at class day three times, a record exceeded by no other faculty member. In 1977, he cited students as a "corrupting" influence in shifting his interest from hard science toward public policy.

"You seduced me into that dreadful scientific error: the substitution of important, unanswerable questions for unimportant, answerable ones," he noted.

In 1969, near the peak of student unrest, he told graduating seniors: "The problems of population growth, of environmental deterioration, of technological overkill are complex. Hearts and bodies are no good against them; only minds are."

After plunging into the political cauldron of saccharin, ice cream, and other food and drug controversies, he told students: "even though one must put up with a good deal of ritual abuse in the regulation business, there is some solace in the fact that in significant part it is ritual abuse. . . . When, in

-more-

the same week, *Business Week* called me arrogant and *Time* called me clubfooted, a friend at the Institute of Medicine said that being Lord Byron isn't all that bad."

After he left the FDA, *The Washington Post* said Kennedy "brought exceptionally articulate and well reasoned argument to. . .often emotional debate." *A New York Times* editorial called him "an exceptionally articulate as well as competent scientist. . . .

"Morale has been raised and the FDA's reputation is decidely one of independence. One measure of the respect that Mr. Kennedy won is that spokesmen for both consumer and industry groups, who seldom agree on anything, rate him equally high."

Kennedy headed the Department of Biological Sciences at Stanford from 1965 to 1972, and later directed the highly respected human biology program. In 1974, he was the first recipient of the Benjamin Scott Crocker professorship in human biology.

Elected to the Advisory Board by his faculty colleagues in 1967, he served as its chairman during 1971-72, presiding at its hearing for former Prof. H. Bruce Franklin.

In less than a year as provost, he moved to improve faculty and staff salaries, created task forces to attract top women professors to the faculty, and took direct personal charge of faculty affirmative action programs.

Last fall, he told the Palo Alto City Council "How well I do will have to be judged by the quality of Stanford faculty in the year 2000. The assistant professors we're trying to appoint and house now will be at or near the peak of their scholarly productivity then."

Knowledge "never gets easier; it only gets harder," Kennedy commented, and it may tend to become progressively more expensive.

"It has to keep getting a little more expensive because it builds on previous knowledge.

"The book of knowledge only grows. You discover that you have new obligations to find out things because you have discovered new tools." Computer science does not displace classics or comparative literature; it becomes an aid to scholars in these disciplines.

In talks with the Faculty Senate last fall, Kennedy said his long term goals as provost included maintaining a balanced budget and attracting "the best student body and faculty in the world" here during the next decade.

The fact that higher education and Stanford face "a tight time" economically should not be "an invitation to a sense of academic helplessness," he added. Kennedy has continued earlier initiatives in forming a new program in public policy.

In 1975, Kennedy headed an ad hoc task force study of extradepartmental programs at Stanford, resolving long standing disputes about how these could best fit the institution's framework. He subsequently served on an Associated Students task force on tenure and teaching quality, whose recommendation for universal course evaluation now has quietly taken effect with faculty approval.

Regarded as a master teacher by several of his colleagues, Kennedy initiated a departmental practice in biology of hiring only one assistant professor for each tenured opening. This meant a greater teaching load for senior faculty, but focused considerable attention on young scholars.

As provost, Kennedy has expressed great concern at possible cutbacks in federal support for graduate students, criticized curtailment of programs benefitting minority graduate and professional students, and noted the rapid obsolescence of many key facilities used in federally sponsored research.

Stanford now ranks third nationally (behind Johns Hopkins and MIT) in dollar volume of federally sponsored research, excluding the Stanford Linear Accelerator Center. The strength of its faculty is reflected in 102 members of the American Academy of Arts and Sciences, 64 in the National Academy of Sciences, 31 in the National Academy of Engineering, 10 in the National Academy of Education, 11 winners of the National Medal of Science, eight Nobel Laureates, and four Pulitzer Prize winners.

New research programs advanced by the faculty include a Center for Integrated Systems, designed to continue U.S. leadership in electronics and related fields; a cardiovascular research center; and the proposed single pass collider project at SLAC, which would achieve collisions at 100 billion electron volts.

Stanford now ranks second only to Harvard in private gift support, receiving a total of $64 million last year, and in its ability to attract those students it admits as freshmen. Stanford's Graduate School of Business and School of Education have consistently ranked first nationally in recent years. The Schools of Engineering, Law, and Medicine usually have ranked among the top three.

Undergraduate enrollment of minority students is at an all-time high. Countering a national trend, first year enrollment of minorities in graduate and professional programs ended a four-year decline last fall.

STANFORD—

Stanford University heart transplant surgeons yesterday expressed cautious support of the federal government's plan to undertake a major study of heart transplantation in the U.S.

The study was announced by Secretary of Health and Human Services Patricia Harris during a press conference June 12 in Washington, D.C.

Purpose of the study is to determine whether heart transplantation can be considered a "medically reasonable and necessary" procedure, and thus should be covered by Medicare.

Until the study begins, all temporary coverage of heart transplantation by Medicare will be withdrawn, Harris said.

Stanford surgeons Drs. Norman Shumway and Edward Stinson said they were not sure what the impact of the withdrawal of Medicare funding would have on the program at Stanford.

Medicare has covered the transplant costs of some Stanford patients on a temporary basis since November, 1979.

However, "we hope the hiatus in funding is as short as possible," said Stinson, head of the transplant team.

Since May, 1979, the Health Care Financing Administration (HCFA), which administers Medicare, in conjunction with the Public Health Service, has been evaluating the Stanford program, to determine whether heart transplantation as performed at Stanford should be covered by Medicare.

However, Harris said, "Although the PHS is continuing its analysis...there are too many unanswered questions to justify a final decision on general Medicare coverage.

"These include the patient selection process, the long-term social, economic and ethical consequences of the procedure, and the potential for national expansion of the heart transplantation procedure."

Harris said that the HCFA will "immediately initiate a broad study of medical, social, economic and ethical consequences of heart transplantation" in conjunction with the National Center for Health Care Technology of the PHS.

According to press reports, she said the study probably would begin in September, 1980, and most likely would involve Stanford.

In addition, Harris said the HCFA will develop by September "a generic definition of (what constitutes) reasonable and necessary medical services."

Finally, she said, HCFA has notified Blue Cross/Blue Shield of California, the Medicare intermediary for Stanford, that "we are withdrawing the tentative authorization granted last November.

"However, those Medicare beneficiaries who received heart transplants and continue in treatment, and those eligible persons already accepted for transplant at Stanford and Arizona will be reimbursed by Medicare for appropriate costs."

(Last month, a Social Security administrative-law judge ordered Medicare to pay for one patient's transplant costs at the University of Arizona in Tucson.)

The Stanford surgeons said the number of patients considered for transplantation at Stanford who are covered by Medicare varies from year to year.

However, patients' private insurance and Medicare are not the only sources of financial support. Stanford surgeons have never charged professional fees for their service, and in addition, portions of a yearly research grant from the National Institutes of Health may be used to defray the costs of transplantation in some patients.

Cost of a transplant, including hospitalization can run from $40,000 to well over $100,000.

STANFORD—

An unprotected child involved in a car accident at just 30 miles per hour suffers the same damage as if he were hurled from the roof of a three-story building.

Such a gruesome scenario, experts believe, is avoidable if parents are educated in the proper use of car seats for children from infancy until they are about four years old.

In fact, says Dr. James Flippen, an associate professor of pediatrics at Stanford University Hospital, the use of car restraints can reduce the number of fatalities among children by as much as 80 percent and decrease injuries by 50-60 percent.

Current statistics, he says, show that 4,000 children die annually on the nation's highway and 200,000 more sustain severe injuries. According to the National Safety Council, this means that automobile accidents have replaced communicable diseases as the No. 1 killer of children over the age of one.

More importantly, adds Dr. Flippen, car accidents are the No. 1 "preventable killer" of children.

Dr. Flippen recently held an in-staff meeting at the hospital on infant auto safety with a representative from the state Department of Transportation. Since October, the state has been operating a "safety-in-transit" program on passenger safety for children.

Federally-funded, the program's main thrust is establishing good safety habits among the parents of newborn children.

"Statistically," says Dr. Flippen, "we find we get the best results involving parents in the neonatal period. . . because they are most susceptible to the needs of their child at the time of birth.

"If proper carriers are used initially, parents tend to continue the habit later on."

To educate parents, the state program suggests infant car seats be made available to new mothers at cost before they leave the hospital; consumer guides, describing acceptable car seats, be distributed; and hospitals display infant child seats in auxiliary gift shops or in maternity wards.

Also, a film, entitled, "The Perfect Gift" can be shown. It underscores the importance of using a car seat the moment an infant is taken home.

Although mothers often feel they can adequately shield their babies by cradling them in their arms, the film show that in an accident, the baby can be crushed by its mother's body or become a human missile, hurtling head first into the dash or windshield.

STANFORD—

Stanford University Hospital has been granted an exception to the 1979-80 limits on reimbursement by the federal government for hospital services provided to medicare patients.

The exception will avoid an estimated loss of $2 million in the hospital's annual income, according to Hospital Executive Director Dr. Peter J. Levin.

(The estimated loss was based on the reduction in reimbursement to Stanford, from $191 to $169 per Medicare patient per day.)

Although the hospital has been paid at the lower rate since last September, Levin said the difference will be made up through higher reimbursements through the remainder of the fiscal year.

The exception was announced recently by the Health Care Financing Administration (HCFA) of the Department of Health and Human Services, which administers the Medicare program.

In a letter to the Blue Cross of Northern California, the region's Medicare intermediary, HCFA official Michael W. Maher stated that the exception takes into account the relatively short average period of hospitalization in California compared with other states, and the higher costs of "more intensive. . . services" provided at Stanford.

"We are very pleased that the HCFA granted an exception," said Levin.

"We were able to prove that nursing services provided at Stanford are more extensive than those provided to Medicare patients in most other hospitals," he said.

Levin added that the exception represents a year of effort by University officials.

In addition, Levin also lauded California Congressman Pete McCloskey and other members of the State's congressional delegation for supporting a change in the regulations.

Currently, the HCFA is considering comments from the nation's hospitals on a proposal to revise last year's regulations, to take into account more fully the costs associated with training physicians.

Although the proposed regulations are greatly improved, Levin said they would still cost the Hospital an estimated $1.4 million in annual revenue.

Stanford has prepared comments on the proposal, but may have to request a further exception next year if the regulations are put into effect in their present form, he said.

CITY DESKS: Photos available on request if not included.

STANFORD—

It has been nearly two years since Tom Streithorst had a heart transplant at Stanford University Hospital, but aside from living in the Bay Area, he has made no real concessions in his strenuous lifestyle.

As of January this year he went back to work full-time as an NBC correspondent; he writes occasionally for several magazines; he reads voraciously; and he is currently in the process of overhauling a 24-foot sloop for a sailing trip to Mazatlan, Mexico, and perhaps eventually, around the world.

He also plans to write a book of memoirs on his career, which will include a segment on his operation and his journey back from what he describes as the "edge of death". A two-part film on his ordeal has been aired by NBC and is considered the first visual documentation of the entire procedure through the post-operative period.

Of course, there are the little things he has had to give up since the operation, like pizza and other junk foods, but as he says, "I'm essentially the same person. . .only more intensely so."

If there is any doubt, one need only visit Streithorst in his hospital room at Stanford, where he recently underwent treatment for an infection. Restless after eight days in bed, he granted an interview, while readying himself to go out on an assignment of his own.

Dressed in corduroy jeans, a light blue button-down shirt and tie loafers, he looked casually elegant. And despite the fact that he claims to be battling a weight problem—("My wife says she married Jack Palance and ended up with Orson Welles")—he is more stocky, than fat.

Only the purplish bruises on his legs and the IV (intravenous) machine, which pumps heavy doses of medicine into his body, attest to the occasional physical discomforts a new heart has caused.

"Prednisone and Imuran", says Streithorst, "are the two (drugs) that keep you alive, but they are also the ones that make your bones fragile and your skin bruise easily.

"If you kiss me, I bleed."

Like all heart transplant recipients, Streithorst must juggle a battery of drugs the rest of his life, because the body never stops rejecting the foreign heart tissue. Ironically, the same drugs which have brought this problem under control, leave patients susceptible to life-threatening diseases because they suppress the body's natural immunity.

Infections are not only common, they are now the leading cause of death among transplant recipients—a statistic which Streithorst treats with proper respect.

"I tend to come in here if something doesn't seem quite right," he says. "Having a weakened immunity systems means anything can go wrong very rapidly."

The precaution of living close to Stanford, he feels, has increased his odds for survival by at least 40 percent.The availability of quick, effective medical attention also has given him a psychological edge, although he is far too busy to brood about death.

"I'm not afraid of dying," he says. "I am afraid of sickness, of limitations. You have to take risks to be. . .to feel alive."

As a foreign correspondent for NBC for 15 years, Streithorst took many risks on the job, including three tours as a war correspondent in Vietnam. He also witnessed many times what he describes as quick, relatively painless, death. It is his repugnance to the other kind of death—slow and degenerative—that ultimately led him to Stanford University Hospital for help.

-more-

To date, some 189 heart transplants have been performed at the hospital—more than anywhere else in the world. Each year, at least 400 patients are referred for transplantation, but only 60 are asked by the transplant team, to come out for further evaluation. Of these, 40 are eventually selected for treatment, but one-third of this number die before treatment can take place.

Without transplantation, all those chosen for the operation would die within a few months. With the operation, there is currently a 70 percent chance of survival the first year, and a 50 percent survival rate of five years.

Streithorst met the medical, as well as the more subtle, criteria of the transplant team with flying colors.

Not only was he considered a good candidate for survival, Dr. Norman E. Shumway, chairman of cardiovascular surgery, called him an "obvious winner"—someone who clearly wanted to do more with his life.

"I was the kind of guy who woke up after the operation and said, 'Oh my God, I'm alive,' now I have to get cracking and do all the things I want to do."

This meant, once Streithorst decided he wanted to return to work, he didn't wait around for NBC to ask him. Nor was he put off by a 1976 study in the *Journal of the American Medical Association* that indicated that some heart transplant patients had encountered hiring discrimination.

Instead, he proposed that NBC rehire him on a six-month trial basis, then if both parties were mutually satisfied, a standard three-year contract could be signed.

"I told them they had been very generous, which they had," he says, "and that they owed me nothing more. . .except the opportunity after 15 years to see if I could still do it."

Although the trial period ends on July 7 this year, NBC has already offered Streithorst a new contract. So it seems clear that he still can do it.

He is no longer a foreign correspondent since it would take him too far away from the hospital, but as a domestic correspondent, he likes to specialize in "eyebrow raisers". These are the kind of stories that combine significance and originality, he says.

It may well be that raising eyebrows is just part of his self-described "audacious" style.

From his hospital bed, he asks a startled nurse to unhook the IV so he can go get a sandwich. "Let your people go," he pleads.

When she won't, he simply walks out of the room with a big smile, wheeling the machine behind him.

CITY DESK: Conference is by invitation only, but reporters are welcome.

STANFORD—

A three-day conference on "Nutritional Care of High-Risk Obstetrical Patients and High-Risk Infants" will be sponsored by Stanford University School of Medicine, department of pediatrics, on June 16 through 18 in the School's Fairchild Auditorium.

The purpose of the conference is to increase the knowledge and awareness of health care personnel in meeting the nutritional needs of both high-risk pregnant mothers and those of the immature and ill newborn infant.

An overview of these problems, entitled, "Nutritional Needs of the Pregnant Mother and Her Fetus" will be given by Dr. Norman Kretchmer, director, National Institute of Child Health and Human Development in Bethesda, Maryland. Formerly chairman of Stanford's department of pediatrics, Dr. Kretchmer established one of the first premature infants research centers in the country.

Dr. Philip Sunshine, professor of pediatrics and director of nurseries at Stanford, will be the program moderator.

Other topics covered in the three-day conference will include: "Human Milk Banking," "Diabetes in Pregnancy,""Immunological and Environmental Factors in Human Milk," "Toxemia of Pregnancy—A Nutritional Disorder" and "Physiology of Lactation."

The conference is funded by a grant from the Department of Health, Education and Welfare.

STANFORD—

Stanford University is sending six medical students and 33 others interested in health care careers to England this summer to study the National Health Service there.

During the eight-week program, the students will reside in Cliveden House 40 miles from London and commute to their medical assignments in the community. Cliveden is leased by the university from the National Trust of England as an overseas campus.

"One of the most important aspects of this program ," says Dr. Count D. Gibson, Jr., the academic coordinator who will accompany the students abroad on June 18, " is that the students will see the National Health Service is not just for poor people.

"Where Cliveden is. . . is hardly a disadvantaged area!"

Dr. Gibson is chairman of the Department of Family, Community and Preventive Medicine. In 1975, he accompanied the first group of medical students from Stanford abroad on an experimental program.

While the program was successful, he says, it proved unwieldy because too many students were involved. So this time, only half the original number are going.

However, the selection process, says Gibson, was "agonizing."

"In the end, we chose the most mature and the most experienced."

Altogether, there were 131 applicants for the program, but only 39 slots. Those selected had to be at least college juniors and have work experience in a health care setting.

Once chosen, all those, except medical students, were required to take a course in the spring on the health care systems of Britain and the U.S., which Gibson teaches. Also, whenever possible, students were exposed to the American counterpart of the institutions they will be studying abroad.

"What's the purpose of all this," asks Gibson rhetorically. " All of these young people are committed to health care careers in the U.S. We hope this exposure will give them a clearer look at our own strengths and weaknesses."

Once abroad, the students will have a two-week orientation period before being sent out into the community to study the various components of the English health care system.

Some of these components include special hospitals where the mentally ill and chronically disabled are treated; acute general hospitals where the medical specialists practice; and district community physicians, responsible for health promotion and disease prevention.

Student assignments will actually be determined by St. Thomas Hospital Medical School in London, which collaborates with Stanford on the program.

Except for transportation costs, says Gibson, the cost of studying at Cliveden will be identical to the cost of room and board in one of Stanford's own dorms.

For their work, the students will receive 15 units of credit from Gibson's department.

STANFORD—

The Division of Ophthalmology at Stanford University School of Medicine has received a grant of $12,500 by the Northern California Society for the Prevention of Blindness for purchase of a new camera used in the diagnosis and treatment of retinal disease.

The grant was made at the request of the I CARE Auxiliary of the Society, which directs a glaucoma screening program in various senior centers and retirement homes throughout the Peninsula.

The new equipment, called a Pomerantzeff equator plus camera, enables doctors for the first time to take a wide angle photograph of the entire retina at the back of the eye. Previously they had to piece together several shots to form a composite view of the retina.

"The new camera will enable us to improve diagnosis of a variety of retinal disorders, including tumors, retinal infections and diabetic retinopathy, a complication of diabetes that can lead to blindness," said Dr. A. Ralph Rosenthal, head of the ophthalmology division.

"We are also very grateful to the I CARE Auxiliary for their generous support of the summer student research fellowship in ophthalmology," he said.

Begun last year, the fellowship provides $1,500 each summer for five years to support research by a medical or premedical student in glaucoma or ocular complications of diabetes.

In addition, ophthamology residents participate in the Auxiliary's glaucoma screening program, and perform the examinations on a rotation basis during the academic year, Rosenthal said.

STANFORD—

Dr. Herbert L. Abrams, chairman of the department of radiology at Harvard Medical School, has been appointed visiting professor of radiology at the Stanford University School of Medicine for the academic year 1980-1981.

Abrams served as head of the division of diagnostic roentgenology at Stanford from 1961 to 1967, before assuming the post at Harvard.

A well known diagnostic radiologist and specialist in coronary angiography, Abrams recently published a study of the dramatic rise in the use and cost of radiologic procedures in the U.S.

The increase is related to a variety of factors, he reported, including undue dependence on radiologic rather than clinical follow-up, defensive medicine, and reimbursement policy.

Abrams received his M.D. from the State University of New York-Downstate Medical Center in 1946, and completed residencies in medicine at Montefiore Hospital and in radiology at Stanford University Hospital before joining the Stanford faculty as an instructor in radiology in 1951.

He served as acting executive of the Radiology Department in 1961, and was promoted to professor the following year.

The author of 150 scientific articles, Abrams is on the editorial boards of several medical journals, and has participated in numerous professional societies and organizations, including the American Association for the Advancement of Science, the American Heart Association, and the Institute of Medicine of the National Academy of Science.

In addition to his academic duties as Philip H. Cook Professor and Chairman of Radiology at Harvard, Abrams is radiologist-in-chief at Peter Brent Brigham Hospital and at the Sidney Farber Cancer Institute in Boston.

STANFORD—

Dr. Julian Davidson has been promoted to professor of physiology at Stanford University School of Medicine.

The author of over 100 scientific publications and two books, Davidson is well known for his studies of the relationship between hormones, the brain and sexual behavior.

Recently he has turned his attention to the study of hormonal and behavioral factors in aging of humans.

A native of Ireland, Davidson received his Ph.D. in physiology at the University of California (Berkeley-San Francisco) in 1959. He was a postdoctoral fellow of the National Institutes of Health (NIH), and did research at Hebrew University in Jerusalem, Israel before joining the Stanford faculty in 1969.

He is a member of several professional organizations, including the Endocrine and Reproductive Biology Study Sections of the NIH. He received a Guggenheim Fellowship in 1970, and a special NIH fellowship to study at Oxford University, England, in 1970-1971.

STANFORD—

Alice Stiebel has made a unique gift to her parents, the gift of blood.

Recently, Mrs. Stiebel of 840 Talisman Drive, Palo Alto, learned that Stanford University Blood Bank gives credit each time blood is donated.

The Blood Bank does not charge a "replacement fee," but will pay for any such fees charged by other blood banks used by patients and their families and friends under its credit system.

Mrs. Stiebel plans to assign the credits she earns for giving blood at Stanford to her parents, Mr. and Mrs. Henry Bauling, also of Palo Alto.

Although they are now healthy, active people in their 70s, "this is a gift in reserve should they ever need it," she said.

The pint she gave for her parents was the first one Mrs. Stiebel had ever donated.

"I had a natural reluctance to part with my blood," she said, "but my aversion was overcome by my desire to help my parents in the future.

"I never had the motivation to give before," she added.

Mrs. Stiebel said she hadn't yet told her parents about the gift. "I'm not doing it for their reaction. I'm doing it for me, as a way I can take care of them."

Ellen Fox, blood donor recruiter at the Blood Bank, said that Mrs. Stiebel's gift is one of many regular donations that help maintain an adequate blood supply for the Stanford Hospital.

Currently, the Hospital uses 100 pints of blood every day.

Further information regarding blood credit policies can be obtained by calling the Stanford University Blood Bank, 497-7831.

EDITORS: Photo of volunteer available if not included with story

STANFORD—

Ten Stanford undergraduates are participating in a unique program this spring as volunteers in the cardiovascular intensive care unit (ICU) at the University Hospital.

The program is designed to help nurses care for critically ill patients with heart disease, while giving the students some "hands on" experience in clinical medicine, according to program director Dr. William New.

New, an assistant professor of anesthesia at the Medical School, conceived the program as a means of helping the undergraduate students he advises decide whether or not to pursue a career in medicine.

Many students are interested in medicine, he noted, but are nervous about taking the premedical curriculum without some sort of "reality testing."

"You can't learn anything about medicine in the undergraduate biology courses," said Eugene Toy, a sophomore electrical engineering major who has been volunteering on the ICU for the past six weeks. "This experience has really convinced me that I want to become a doctor."

Toy plans a combined career in medicine and electrical engineering. Other student volunteers are majoring in chemical engineering, biology, and human biology, although only three of the 10 have New as their advisor.

In the ICU, students can observe the care of patients just back from open heart surgery, and perform some nursing assistant tasks, such as helping nurses turn patients in bed or attending patients as they walk around the unit.

They do not perform direct patient care which requires professional training, and are under constant supervision by the nurses or nursing assistant.

In addition, all of the students joined the Hospital Auxiliary, which provides insurance coverage to volunteers who work with patients.

"They are probably the most knowledge-thirsty volunteers the Hospital's ever had," said program director New.

"It is shocking at first to see really sick patients," said Taylor Chung, a junior who enlisted other students in the program and organized their schedules so there is volunteer coverage five evenings a week.

-more-

"Some of us had butterflies in our stomachs," he said, especially when confronted with patients just back from open heart surgery who have the zipper-like scar from neck to abdomen and drainage tubes in their chests.

But the queasiness disappeared as they became involved with the nursing and medical staff.

"They take a big load off my shoulders," said John Marcello, the unit's only nursing assistant in the evenings. "I work with 25 nurses in what can be a very demanding job."

"The students have been really willing to learn and to help out," adds Libby Travers, R.N. "They're the kind of people you want to see as doctors."

New says he has received no negative repercussions from the program. The doctors and nurses like to have the students around, and, of course, the patients get more attention than they would otherwise.

However, it is unclear how much legal liability the volunteers carry, said Kathy Rawlins, R.N., if, for example, they help walk a patient and the patient falls.

That question should be resolved when the program is evaluated this summer, she added.

Although the ICU will lose its student volunteers when the school year ends in June, New said he hoped it would be established on a more permanent basis in the Fall.

There certainly is no lack of interest, he added. "I must have 20 students who want into it, far more than I advise."

New said that student volunteers seeking experience in medicine could help nurses in other areas of the hospital, such as the intensive care nursery and operating rooms.

"Here is a tremendous reservoir of interest and abilities," he said. "The real problem is finding some place to capture that energy and use it."

Negotiations for a new contract between Stanford University Hospital and CRONA (the Committee for Recognition of Nursing Achievements) began Tuesday, May 20.

CRONA is the professional organization which represents over 1,000 of the Hospital's non-supervisory staff registered nurses.

The current agreement will expire on June 30.

"We hope to reach an agreement before the deadline," said Joanna Nelson, R.N., chief negotiator for CRONA.

Other members of the CRONA team are registered nurses Hedy Dumpel, Patricia Tharp, Mary Durando, Melba Simpson, and Alice Serbein.

The Hospital is represented by Priscilla Wheeler, chief negotiator from the University Counsel's Office; Don Thomas, director of Personnel Services; Carol Ann Bergman, manager of labor relations; Nancy Madsen, R.N., associate director of Nursing Service; and Joyce Miller, R.N., and Jeanne DeJoseph, C.N.M., assistant directors of Nursing Service.

STANFORD—

Crowded rooms, the rattle of carts, noisy visitors and the midnight pill or shot.

Patients are still listing traditional grievances among the chief irritants of hospitalization, according to a survey at the Stanford University Hospital.

But, on the plus side, physicians and nurses continue to rate surprisingly high with the patients they take care of, despite much recent criticism of the health care establishment, according to the survey.

The highly positive attitude toward the quality of medical and nursing care was one of the chief findings of the patient and community attitudes survey program instituted by the hospital.

Until the poll was initiated by the 668-bed university hospital, administrators, doctors and nurses could only guess at how patients really felt about the care they were getting, food, their hospital environment, their room or ward, financial matters and other aspects of being sick and under treatment in a large health care and research institution.

The survey questionaires and polling techniques which included not only patients and the community at large, but the hospital's entire medical staff were put together by Decision Research Institute.

According to Hospital Executive Director Dr. Peter Levin, the survey was commissioned in order to evaluate how the community, patients, and the medical staff perceived the effectiveness of the hospital's operation.

"It is an opening step in our efforts to improve services to patients and the community," Levin said.

One survey—May 1979—of 3,700 former patients, with results based on 959 usable questionaires shows that patients were generally more satisfied with the quality of their care and with the attitudes of their doctors and nurses than was thought to be the case.

For example, when asked to rate nursing care as "poor," "fair," "good," "very good," or "excellent," 75% of the responding patients evaluated nursing as "very good to excellent," with 13% "good" and 5% only "fair."

When the patients were asked if nursing procedures were explained before being carried out, if lights or call bells were answered promptly, and if requests were promptly filled, about 4 in 10 responded that this was always the case, while an additional 30% noted frequent occurence.

"Physician care was generally highly rated," the survey report noted. Better than 8 in 10 (86%) of the patients considered the treatment and attitude of their personal physician to be "very good to excellent."

Interns and residents received only slightly lower marks, with 78% of the patients evaluating them as "very good to excellent."

This finding of high acceptance of interns and residents by the patients is significant, Levin said, since Stanford University Hospital is a teaching institution with many of them on the floors each day to gain clinical experience.

Stanford serves both as a community and a teaching hospital, with community and faculty physicians on the staff. The differing objectives of the two groups have often led to town-gown friction. Predictably, the views of the two groups differed in some respects.

Seventy percent of the faculty physicians said their patients regarded the hospital as "above average to superior" versus 44% of the community doctors who shared this opinion. Community physician ratings were clustered more at the lower end (24% "average," 14% "below average," and 3% "inferior."

Community physicians (25%) said town-gown conflicts were a major problem, and 11% of both community and faculty doctors were critical of past administrative leadership.

However, both community and faculty physicians (53%) agreed that the quality of medical care is high. It is for the most part, the support services, such as medical records (file room and transcription), administration, cafeteria, emergency department, and operating room facilities among others, that were considered average.

Stanford's reputation, quality of medical care and medical staff, and advanced technology are viewed by physicians, patients, and the community as the hospital's strongest points.

Community, former patients, and physicians cited impersonal care in some cases as the most common weak point.

Costs also came under criticism. Four in 10 (43%) of the patients found the cost of their care to be higher than they had expected, and 23% said the costs were excessive for the quality of services provided.

Levin sees use of the information gathered not only for making immediate changes as necessary, but also for long range planning, to incorporate the patient's and the physician's viewpoint as the hospital changes and develops.

Already, he points out, the need for better relationships with the hospital's many constituencies led to the appointment of a community relations director, followed by development of a patient relations program as a next step. There have been changes in the food service management, and in the organization of the admitting department.

And a new publication was started to improve communication with physicians.

"The physical facilities of the hospital give rise to much dissatisfaction on the part of physicians and patients," Levin said.

"One major action in this area has been the development of a multi-million-dollar modernization plan to correct deficiencies, and add space and operating rooms. Also renovation of patient rooms is being considered, including provision for more private rooms which, according to the survey, patients want.

The survey included 807 physicians on the staff who were mailed questionaires in February 1979. The response rate was 65.9%. Face-to-face interviews with a random sample of 136 physicians on the staff were also conducted.

In addition, 800 residents from the hospital's primary and secondary service areas (San Mateo to San Jose) were contacted in telephone interviews.

STANFORD—

Stanford University Hospital has received two-year accreditation from the Joint Commission on Accreditation of Hospitals (JCAH) and California Medical Association (CMA) consolidated survey, according to Dr. Peter Levin, Hospital executive director.

Two years is the maximum period of accreditation granted by JCAH.

The survey team visited the Hospital March 17-19, inspecting many aspects of patient care, documentation of medical care, physical plant and facilities, safety and space, management and administrative operations, medical staff organization and nursing service, and laboratory procedures.

"We are very pleased," Levin said. "What was obvious from the survey is that the Hospital is operating at a high level of practice, and the quality of our operations came through."

The JCAH report to the Hospital listed a number of recommendations on areas to be improved prior to the next survey. Many of the technical recommendations are already being put into effect, Levin noted.

One recommendation suggests that the two separate radiology departments be combined to avoid duplication of services. Presently one department serves community physicians and another serves university faculty.

This recommendation is under consideration, Levin said.

California State Health Department representatives also participated in the survey for licensing purposes.

The purpose of the survey is to help hospitals maintain highest quality health care, according to the JCAH.

The JCAH is a private, nonprofit organization governed by the American College of Surgeons, the American College of Physicians, the American Dental Association, the American Hospital Association, and the American Medical Association.

FOR FURTHER INFORMATION CONTACT: Spyros Andreopoulos (415) 497-6911

STANFORD—

Researchers at Stanford University School of Medicine have succeeded for the first time in growing human hybridomas, artificially created cells that produce pure or "monoclonal" antibodies.

Antibodies are highly specific molecules that often form the body's first line of defense against viruses, bacteria, and other foreign invaders.

Hybridoma technology at present produces mouse antibodies. These, according to researchers, are not the first choice for diagnosis and treatment because of the body's natural reaction against foreign proteins.

Therefore, the development of pure antibodies from human cells is considered to have far-reaching implications both as a powerful tool for studying human disease, and as a method for rapid diagnosis of virus and bacterial infections, and detection of cancer.

A long-range goal of researchers in the field is to use monoclonal antibodies for therapy as vaccine replacements and in the treatment of diseases ranging from hepatitis to cancer.

The method for making human monoclonal antibodies was developed by Dr. Lennart Olsson, a Danish Medical Research Council Fellow now at Stanford, and Dr. Henry S. Kaplan, D'Ambrogio Professor of Radiology and director of the Cancer Biology Laboratory.

Kaplan reported on the research last week at the International Congress of Immunology in Paris, France.

"In principle, this method should permit generation of human monoclonal antibodies against a broad spectrum of predefined antigens," Kaplan said of the work which was sponsored by grants from the National Cancer Institute.

Antigens are protein-linked substances that stimulate the body to produce antibodies as diseases do.

Olsson and Kaplan produced the human antibody molecules using a human myeloma cell line (bone marrow cancer cells) developed by Dr. Kenneth Nilsson of the Wallenberg Laboratory at the University of Uppsala, Sweden.

The key to their success, however, is that they primed the human cells chemically to select a mutant cell line that propagates in the test tube more readily.

-more-

Next the researchers fused the mutant cells with the uninvolved spleen cells of patients with Hodgkin's disease who had undergone splenectomies (removal of the spleens) at Stanford University Hospital.

At least two weeks prior to surgery, such patients are routinely submitted to immunologic tests, and they are sensitized with a chemical 2-dinitrochlorobenzene (DNCB).

As a consequence their spleen cells produce antibody to DNCB. The hybridoma or hydrid cell so formed by the fusion process has some of the features of the spleen cells (producing antibody to DNCB) and some of the features of the primed myeloma cells (rapid and continuous growth).

Kaplan cautioned, however, against premature optimism about the technique.

"The only antigen used in the present study was DNCB," he said. "The ultimate importance of this method will depend on the spectrum of antigens against which human monoclonal antibodies can be produced."

Experience with mouse hybridoma techniques have indicated the antibody spectrum to be considerable, Kaplan said, but this technique is also facilitated by optimal immunization procedures and unlimited supply of mouse spleen cells.

More work is necessary to determine if human monoclonal antibodies to a broad spectrum of antigens can be produced in the test tube, he added.

Mouse monoclonal antibodies were first produced in 1975 by Dr. Cesar Milstein of the Medical Research Council in Cambridge, England, and his former colleague, Dr. Georges Kohler, now in Basel, Switzerland.

Their invention has led to development of an important biotechnology industry. Mouse monoclonal antibodies are sold for research only, including certain limited clinical trials.

According to Niels J. Reimers, director of the Office of Technology Licensing at Stanford, steps are being taken to make the human mutant cell line developed by Olsson and Kaplan available to other researchers through the Salk Institute in La Jolla.

In addition, Stanford will make arrangements to make the cell line available to commercial companies interested in the process.

STANFORD—

Stanford University Hospital's Disaster Preparedness Committee wants all Hospital employees to "think disaster" Tuesday, July 29.

At 10 a.m., a disaster drill announcement will be broadcast over the telepage system, all departments will activate their disaster plans, and a carefully orchestrated drill will test the Hospital's response to a make-believe calamity.

The disaster scenario involves the crash of a 727 commercial airliner in the Palo Alto baylands, shortly after takeoff from the San Jose Airport. When the pilot attempts a water landing, the fuselage breaks open, and many people are injured. In addition, a fire in the forward compartment of the plane causes several burn casualties.

This type of scenario provides "patients" with multiple injuries, according to Associate Administrator Don Utt. About 30 moulaged volunteers (with makeup applied to simulate real injuries) will move through the patient care system. Volunteers are from the Palo Alto Boy Scouts, the San Mateo County Explorer Scouts and the Stanford Medical Center Auxiliary.

Paramedics from Palo Alto will assist in transportation, along with the St. Clair Ambulance Service. Two Coast Guard helicopters will also participate in the drill, to exercise procedures for transfer of patients to the Hospital from the helipad on Welch Road.

One major goal of the drill is to orient new house staff physicians to the Hospital disaster plan, according to Dr. Jan Ehrenwerth, of the Disaster Preparedness Committee, who is coordinating the drill.

But the Committee also hopes to stimulate broader interest in disaster preparation.

The probability of a major Bay Area temblor has been set at 50 percent during the next ten years by several earthquake prediction specialists.

Because of the catastrophic effect this could have on the community, the Committee has set another drill next February to specifically test the Hospital's ability to respond to a major earthquake.

In addition to exercising the Hospital's internal response, the February drill will evaluate evacuation readiness and procedures for moving patients to University and community resources such as Cowell Student Health Center, the Surgicenter, and a 200-bed packaged field hospital owned by Santa Clara County and stored at the University.

The Hospital conducts at least two disaster drills annually.

STANFORD—

Dr. Frederick A. Fuhrman, professor of physiology at Stanford University School of Medicine will become professor emeritus, effective Janaury 1, 1981.

Fuhrman, who has been on the medical school faculty since 1941, studied in his early work the effects of temperature on biological processes.

For the last 15 years he has worked with biologically active natural products from animals, emphasizing marine forms. Early in this research with Dr. Harry Mosher of the Department of Chemistry, he discovered that the California newt contains tetrodotoxin, an extremely toxic substance previously known only in the Japanese pufferfish.

Tetrodotoxin, a non-protein toxin is easier to handle than a protein toxin. It is widely used in research and can be modified to treat diseases, he said. This toxin is 60 times more powerful than strychnine or curare, and even a tiny amount can kill a man.

Tetrodotoxin is rivaled in toxicity only by kokoi venom found in certain south american frogs, saxitotoxin found in certain clams and mussels, and palytoxin from a marine invertebrate animal.

According to Fuhrman, "just because a compound is toxic, one need not assume that it is not useful. Different dosage levels and modification of the molecule can often make a very useful drug from the original poison."

Fuhrman is currently studying shell-less marine snails related to the common garden slug. He and his wife Geraldine, a research associate, are trying to isolate pure chemical compounds in these and related animals to find their effects.

One compound which has been isolated from the marine snail is called doridosine. A new hypotensive drug, doridosine reduces the blood pressure and heart rate. So far it has only been tested on guinea pigs and mice, with the animals recovering completely after being injected with the compound.

Fuhrman, who believes that "the interaction between biology and medicine is important," was associated with Hopkins Marine Station at Pacific Grove, California for seven years. During his stay he continued his research with marine animals.

-more-

As director of the Max C. Fleishmann laboratories at Stanford for 10 years, Fuhrman said the role of the labs were to "provide facilities and materials to students for study and individual research." The concept was to provide an area where students could take a group of classes from chemistry to cell biology without leaving the labs.

Under these conditions the professors would go to the students so that the students could study more effectively. Today, because of a lack of student interest, the labs are operating on a smaller scale.

Born in Coquille, Oregon, Fuhrman received the B.S. and M.S. from Oregon State University in 1937 and 1939, and the Ph.D from Stanford in 1943.

His many honors include a Guggenheim Fellowship, during which he worked in Copenhagen, a senior postdoctoral fellowship from the National Science Foundation and a fellowship from the Commonwealth Fund.

He is a member of the American Physiological Society, Society of General Physiologists, Society for Pharmacology and Experimental Therapeutics, and is a fellow of the American Association for the Advancement of Science.

A prolific author, Fuhrman has contributed articles to the *American Journal of Physiology, Science*, the *Journal of Pharmacology and Experimental Therapeutics* and the *Journal of General Physiology*.He has also written for the *Encyclopedia Britannica* and *Scientific American*.

STANFORD—

A two-day conference on the use of computers and applications of "artificial intelligence" in medicine will be held August 17 through 18 at the Stanford University School of Medicine.

Co-sponsored by the Division of Research Resources of the National Institutes of Health, the conference will begin at 8:15 a.m. in Fairchild Auditorium.

Among topics will be an overview of the uses of artificial intelligence in diagnosis and treatment, and SUMEX-AIM, the nationwide, federally-sponsored computer network now providing much of the impetus for this work.

SUMEX-AIM stands for Stanford University Medical Experimental Computer-Artificial Intelligence in Medicine. It was co-founded by Dr. Joshua Lederberg, now president of Rockefeller University in New York, and Professor Edward Feigenbaum, chairman of Computer Science at Stanford.

Artificial intelligence refers to the emerging capabilities of computers to reason symbolically with the use of specialized knowledge.

Many of the computer programs that now use artificial intelligence for biomedical research and decision making have evolved within the SUMEX-AIM computing system, according to Edward H. Shortliffe, program chairman.

He said the conference is aimed at physicians to familiarize them with applications of artificial intelligence techniques, and the future promise of this field in medicine and biomedical research.

Twenty years ago, explorations in artificial intelligence were limited to mathematical exercises and games of chess.

In the mid-1960's, researchers began to apply the computer's "brain" to solving tough problems in chemistry and biology.

The advantage of a large, time-shared system like SUMEX is that it permits rapid interactions and cooperation between many research groups in fields ranging from organic chemistry to medical diagnosis.

One example of artificial intelligence research which will be reported at the meeting is INTERNIST. Developed by Dr. Jack Myers and computer scientist Harry Pople of the University of Pittsburgh, it is a program that mimics the reasoning used by physicians to diagnose disease.

When perfected, this system will be able to assist physicians seeking advice on difficult medical problems as well as paramedics serving in remote or underserved areas.

Another example is MYCIN, the work of Dr. Shortliffe and Dr. Bruce Buchanan. In collaboration with Drs. Stanley Cohen and Stanton Axline, they have developed a program to help physicians diagnose infectious disease and prescribe treatment.

A third application of artificial intelligence research will be discussed by Dr. James Fries of Stanford's Department of Medicine and Dr. Robert Blum of Clinical pharmacology. It is the use of computerized data banks to study chronic diseases such as cancer, heart disease and stroke, the various treatments, laboratory tests, and the complex relationships among them.

Other talks will focus on "human engineering" issues on how computers can be made more attractive and accessible to physicians.

The computers in medicine program is held in conjunction with the First Annual National Conference on Artificial Intelligence which will be held on the Stanford campus August 18 through 21 immediately following the medical meeting.

TO: SCIENCE WRITERS AND CITY DESKS

Stanford University will play host to two major conferences on Artificial Intelligence in August.

The first of these is a two-day meeting on the use of computers and applications of artificial intelligence in medicine scheduled at the Stanford University School of Medicine August 17 through 18.

The meeting, co-sponsored by the Division of Research Resources of the National Institutes of Health, will provide state-of-the art reports on the uses of artificial intelligence in medicine, and the role of SUMEX-AIM (Stanford University Medical Experimental Computer-Artificial Intelligence in Medicine). This nationwide federally funded facility is providing much of the impetus for this work.

The second meeting is the first annual National Conference on Artificial Intelligence (AAAI) August 18 through 21. AAAI is a new scientific society composed of experts in the field.

Topics will range from robotics to communicating with computers through natural language.

A trade fair demonstrating the latest "hardware" and "software" available will be held in conjunction with the conference (see accompanying stories).

You are cordially invited to attend the meetings. If you plan to come, please fill out the form below and the program, including the NIH publication, "Seeds of Artifical Intelligence," published by the Division of Research Resources will be sent to you. Return to:

STANFORD—

Roberta Joyce Navickis has been appointed science writer in the Stanford University Medical Center News Bureau. Her appointment is effective Aug. 4.

She will succeed Bill Snyder who is leaving Stanford to become reporter for the *Nashville* (Tenn.) *Banner.*

Navickis, 33, is a graduate of the University of Illinois, with a Ph.D. in reproductive endocrinology. For the past two years she has been a postdoctoral research fellow in the Department of Reproductive Medicine, University of California-San Diego.

Combining a background in science and journalism, Navickis has worked for *Science News* in Washington; the *San Francisco Chronicle* as an intern of the Council for the Advancement of Science Writing, and has published articles geared for the layman in many other newspapers and magazines.

In 1976 she was a mass media intern of the American Association for the Advancement of Science in Washington.

Navickis has conducted research in hormones and cancer, ovarian endocrinology, interactions of hormones and vitamins, and calcium transport.

And she has taught courses in cell biology and genetics.

STANFORD—

Dr. Thomas Raffin has been appointed assistant chief of medicine for clinical programs, a new post in the department of medicine at Stanford University School of Medicine.

The new position was created "to coordinate the department's increased commitment to clinical medicine and teaching," said Dr. Kenneth Melmon, in announcing Raffin's appointment.

"The quality of research, teaching and patient care in the department of medicine has always been outstanding," Raffin noted. "This new position will ensure that clinical programs remain innovative and strong."

Among Raffin's responsibilities will be close involvement with the department of medicine's house staff training program, assisting in the department's medical student education activities, and planning and coordinating new clinical programs in the department of medicine, Melmon said.

For example, the department is creating closer ties with physicians in the community through more effective consultation and referral service, Raffin said.

Another aspect of the strengthening relationship between Medical School faculty and community physicians is the department's steering committee, composed of both faculty and community physicians. The steering committee will assist in giving direction to the assistant chief of medicine, Raffin noted.

Raffin, assistant professor of medicine in the division of respiratory medicine, is also associate director of the intensive care units and medical director of the Hospital's department of respiratory therapy. He graduated from Stanford Medical School and did his house staff training at the Peter Bent Brigham Hospital in Boston. He joined the faculty following a three year fellowship in respiratory medicine at Stanford.

He is the 1980 recipient of the Henry J. Kaiser Foundation award for excellence in clinical teaching, presented by the graduatng class of medical students.

STANFORD—

Stanford University researchers have converted a technique for studying chemical compounds into a precise "meter" of the metabolic status, or healthiness, of organs such as the kidney and brain.

For the first time, mild, reversible physiological changes have been measured in animals without invading the tissues, by nuclear magnetic resonance (NMR), a spectroscopic method used in chemistry to identify compounds and study molecular structure, said Dr. Oleg Jardetzky, director of the Stanford Magnetic Resonance Laboratory.

Aided by grants by the National Institutes of Health—Division of Research Resources and by the National Science Foundation, the experiments so far have been confined to animals, but "there is no question in my mind that the technique is feasible in humans," he said.

NMR could be used to study conditions in which brain damage is suspected, as in cases of near drowning or asphyxiation during delivery, he said. In addition, the technique could be used to determine the healthiness of donated organs, such as kidneys or hearts, before they are transplanted.

"Here is a chemical handle to assess the metabolic competence of an organ, or an animal, or a patient," said Jardetzky, also a professor of pharmacology at Stanford Medical School.

Other methods for monitoring metabolism rely on blood tests, which cannot tell what is happening inside the cells of certain organs, or other tests which damage the measured tissue.

Jardetzky reported on the Stanford experiments Monday, July 14, at a symposium on noninvasive monitoring methods at the 28th International Congress of Physiology in Budapest, Hungary.

The work was conducted by Jardetzky and his colleagues, David Wemmer and Norma Wade-Jardetzky, in collaboration with Dr. Eugene Robin and Dr. Michael Weiner of the Department of Medicine at Stanford.

NMR spectroscopy measures radiation absorbed by the nuclei, or central cores, of various atoms when the elements are placed in a magnetic field. Chemical compounds can be identified by the pattern of lines of their absorption spectra.

The technique has been used by chemists since the 1950s. However, "you can observe nuclear resonance in cells, organs, tissues, animals, and even humans, just as you can in chemical compounds," said Jardetzky, who first used NMR to take physiological measurements of sodium levels in blood in 1956.

Similarly, he added, by taking a reading of the phosphate content of tissues with NMR, scientists can assess their metabolic competence.

more-

This was first done in 1974 by Professor G.K. Radda and his colleagues at Oxford University.

Phosphate, when bound to other molecules is the way the body stores energy in chemical form. Phosphate bound to one type of molecule, adenosine, is an immediately accessible form of energy, "the checking account of the body's energy," Jardetzky said. When phosphate is bound to other molecules, it forms an energy reservoir, or "savings account."

Metabolism actually can be defined in banking terms, as the balance between storing and using energy to perform the various tasks necessary for life.

Jardetzky and Dr. Michael Weiner, now at the University of California School of Medicine in San Francisco, and their colleagues, demonstrated that this energy balance can be measured accurately in a single organ, the kidney, in rats by taking NMR readings of the organ's phosphate content.

In an experiment with freshwater turtles, conducted with Dr. Eugene Robin, acting chairman of physiology at Stanford, the scientists followed changes in brain metabolism as the animals dived, and became deprived of oxygen.

The second experiment has particular application to patients, such as near drowning victims, who may have suffered brain damage due to oxygen deprivation.

Currently, physicians are limited in making a diagnosis of brain damage to performing blood chemistry tests and observing the patient.

"If a patient's blood is depleted of oxygen, you know something is wrong," Jardetzky said. "But you don't really have any direct access at all to what is happening chemically inside the brain."

NMR spectroscopy provides a totally noninvasive method of diagnosing and monitoring not only oxygen depletion but other metabolic disorders as well, he said.

Jardetzky said although it is possible to do NMR spectroscopy in patients, "it is not feasible with the present equipment."

The advent of clinical studies will depend on approval by human subject committees, as well as provision of funding to build the necessary equipment, he said.

However, "I would not be surprised if in the next 20 or 30 years we had the instruments capable of creating a metabolic picture of the body," he added, similar to the way radiography forms pictures of the skeleton, and computerized tomographic (CT) scanners create images of the body's soft tissues.

Editors: Photos of Mrs. Cybulski available if not included with story.

STANFORD—

The day she was discharged from Stanford University Hospital the sign in the window finally came down.

It read, "Please bring me a pizza."

Its light-hearted appeal contrasted sharply with the serious medical problems that kept Carol Cybulski bedridden for more than a year in one of the longest stays in the hospital's history.

But the sign became a symbol of hope for family and friends who waited out her slow and painful recovery.

The 32-year-old Paso Robles woman, who was admitted to Stanford May 3, 1979 and not released until June 23 this year, had developed severe abdominal complications following a hysterectomy in a community hospital.

There were so many tears in her intestinal wall that 20 operations were needed to repair the damage. She was unable to eat anything until two weeks before her discharge and the pain from all the surgery was so enormous, she became temporarily addicted to narcotics.

And last December, she developed blood poisoning and for four months lay in intensive care, near death.

That she didn't die is due, in part, to an immeasurable quality that each patient has—the will to live. But what can be measured and played an indisputable role in her recovery was the support of her family and the medical personnel who took care of her.

"They're an extremely close family," says Claire Mailhot, clinical nursing coordinator on West 2B where Mrs. Cybulski lived most of the past year.

"Their support and the constant care of the nurses on our staff definitely helped pull her through all if this."

On the day of her release, Mrs. Cybulski lay quietly on her bed and joked about all the offers of pizza she has had. Even now, she couldn't eat one, since she is still on a soft food diet.

And sometime next year, according to Mailhot, she will have to come back to the hospital for the final repair work on her intestinal wall.

But none of this seemed to matter.

Surrounded by her family and the nursing staff, who streamed in and out her room with warm wishes, she looked happy and relieved to be getting out.

Her parents, Gene and Helen Gibbs were there, as they has been every day of her illness. So was her husband, Mike who called every day and commuted 180 miles from Paso Robles on the weekends with the couple's children, Michael, 8 and Stephanie, 14.

The enormous strain the family has been under is apparent in Gibbs' rather terse description of his grandson:

"He's eight going on 25. . . If they had let him, he would have helped with the surgery."

Yet the mood of the day was perhaps captured best by the words on a cake the nursing staff had made for Mrs. Cybulski's farewell luncheon.

In bright green lettering, it read, "We've come a long way, Baby."

And indeed, they had.

STANFORD—

Registered nurses at Stanford University Hospital, represented by the Committee for the Recognition of Nursing Achievements (CRONA), have ratified a new 20-month contract with the Hospital, it was announced Tuesday, July 8.

Principal provisions of the contract include a 12% wage increase, retroactive to June 22, a 3% increase on March 1, 1981, and a 9% increase on July 1, 1981.

Additional provisions of the new contract include an increase in the night shift differential from 12 to 14%, and improvements in educational and retirement benefits.

According to Priscilla Wheeler, chief negotiator for the Hospital, the contract was shortened from the previous length of 24 months to 20 months, to improve the Hospital's ability to compete in recruiting nurses with other area hospitals, whose contracts have had expiration dates earlier than Stanford's.

Dr. Peter Levin, executive director of the Hospital, said the negotiations, which began May 20, were conducted "with a mutual sense of cooperation."

Negotiating teams reached tentative terms late Sunday evening, July 6, after a day-long meeting called by Ruth Carpenter, a federal mediator.

Nurses ratified the contract by a two to one margin during an election held Monday and Tuesday. CRONA represents more than 1,000 of the Hospital's non-supervisory staff nurses.

Earlier, the nurses had rejected by a narrow margin a tentative agreement worked out by the Hospital and CRONA with the assistance of the federal mediator.

Originally, CRONA, whose contract expired June 30, had notified the Hospital of its intention to strike July 4 if an agreement was not reached by that time. However, the deadline was later extended to July 8, then rescinded, and a new notice of intent to strike July 14 was given.

Meanwhile, the Hospital took steps to reduce its census in anticipation of a possible strike, from 576 patients on June 26 to under 250 as of July 5. The number was expected to drop to 100 if a strike could not be averted.

Over the Fourth of July weekend and through Tuesday, emergencies and elective patients were admitted only if they could be out of the Hospital before the strike deadline.

Not surprisingly, "the Hospital has a backlog of admissions," said Hospital Administrator Gary Mecklenburg today. However, "we will be working closely with the medical staff in order to admit their patients as soon as possible."

Members of the CRONA negotiating team included Joanna Nelson, R.N., chief negotiator, and registered nurses Hedy Dumpel, Patricia Tharp, Mary Durando, Melba Simpson, and Alice Serbein.

The Hospital was represented by Priscilla Wheeler, chief negotiator from the University Counsel's Office; Don Thomas, director of Personnel Services; Carol Ann Bergman, manager of labor relations; Nancy Madsen, R.N., associate director of Nursing Service; and Joyce Miller, R.N., and Jeanne DeJoseph, C.N.M., assistant directors of Nursing Service.

STANFORD—

Stanford University School of Medicine and the Speech and Language Clinic will part ways August 31 after 20 years of operating a state-wide program for patients with communications disorders.

The clinic, however, will be reorganized as a private professional corporation and will continue independently to serve the patients of Stanford, the Palo Alto Medical Clinic, Children's Hospital at Stanford and a number of extended care facilities in northern California.

The new clinic will be directed by Dr. Kathryn R. Beadle and Donna Dagenais who have developed the program in its present form over the past 10 years.

The clinic, now situated at 600 Willow Road, will move to a new Palo Alto location to be announced later, said Dr. Beadle. It will also have a new name, "Speech and Language Clinic of the Midpeninsula."

The reason for the split was given in identical statements by Dr. Beadle and Dr. John A. Collins, professor and chairman of the Department of Surgery, to whom the clinic has been administratively responsible.

"It is simply a matter of economics," they both agreed.

In 1970 rising costs forced the Medical School to abandon its academic program of training specialists in speech and language disorders. The speech clinic, however, was retained to serve hospital and community needs. It was hoped it could become self-supporting.

While the clinic today is one of the busiest at Stanford, it cannot compete effectively as part of the academic medical center with its associated costs.

"The clinic would be more flexible and efficient if it were separated from the School," Collins said.

He stressed, however, that the clinic's relationship with the School of Medicine would continue as a major referral source for this type of service.

Dr. Beadle added the services which the clinic offers are desperately needed and are a part of total patient care. She plans to further increase the responsiveness to community needs.

The clinic sees patients from infancy to old age. Among them are stroke patients, victims of head and neck cancer, people with voice and fluency disorders, children with birth defects and others with a variety of developmental speech and language disorders. During recent years educational testing and some tutorial help has been offered for learning-disabled students.

-more-

Stanford opened a Speech Clinic on the campus as part of the Department of Speech and Drama in 1932.Shortly thereafter, the first courses in speech correction were taught and programs in audiology and the speech sciences were added.

The activities gradually expanded into a Division of Speech Pathology and Audiology as part of the School of Medicine when the latter was moved from San Francisco to the main campus in 1959.In the late sixties the division was abolished and the programs were split—hearing sciences under the Division of Otolaryngology, and Speech and Language under the Department of Surgery.

"Even though the clinic will be independent, the strong affiliations we hope to develop will enable us to provide an excellent caliber of diagnostic and treatment programs in all age groups,"said Dr. Beadle.

She will retain her clinical faculty appointment in the Medical School.In this position she will participate in teaching physicians, nurses and staff in the hospital. Continuing education programs for speech pathologists, paraprofessional groups and patient families will also be offered at the new clinic, she said.

While the program signals the end of an era at Stanford, Dr. Beadle said she is confident the new Speech and Language Clinic of the Midpeninsula will continue to provide even better services to a far greater number of patients.

STANFORD—

Dr. Henry S. Kaplan of Stanford University School of Medicine has been awarded the Meyer and Anna Prentis Award for outstanding contributions to cancer research by the Michigan Cancer Foundation (MCF).

Dr. Kaplan, D'Ambrogio Professor of Radiology and director of the Stanford Cancer Biology Research Laboratory, received a medal and $1,000 on June 12, during an international carcinogenesis workshop in Detroit.

The workshop, on environmental agents which may cause cancer, was sponsored by the MCF and the National Cancer Institute.

Dr. Kaplan received the award in recognition of his pioneering work on the treatment of Hodgkin's disease and other cancers, and for his "important discoveries in the fields of leukemia and lymphoma research," and "equally significant contributions to experimental radiobiology."

The Prentis Award is given periodically in honor of the late Meyer L. Prentis, former treasurer of General Motors Corporation, and his wife, Anna.

The Michigan Cancer Foundation supports research on the causes and treatment of cancer, and provides a variety of medical services in the Detroit area, including cancer screening and detection, and health education.

In addition to the Prentis Award, Dr. Kaplan recently served as the William Kerr Memorial Lecturer of the Gold-Headed Cane Honor Society of the University of California Medical School in San Francisco, and as the Frederick Stohlman, Jr., Memorial Lecturer during a symposium on "Modern Trends in Leukemia" at Wilsede, Germany.

He was the invited guest lecturer at a symposium on cancer research sponsored by the Australian Academy of Sciences in Canberra, Australia, on May 2, and was a visiting professor in the department of radiation oncology at Johns Hopkins Medical School in Baltimore in April.

EDITORS: The following story is released jointly by Mt. Zion Hospital and Medical Center and Stanford University School of Medicine.

STANFORD—

A unique fellowship, which enables Israeli physicians to study in the U.S., has been established at Stanford University School of Medicine and Mt. Zion Hospital and Medical Center in San Francisco.

The fellowship is in hematopathology, the study of cancers of the lymphatic system, including the bone marrow.

It was conceived by Dr. Ronald Dorfman, professor of pathology and co-director of the Surgical Pathology Department at Stanford, during a trip last year to Israel.

During the trip, "I clearly recognized many of the obstacles facing the medical schools in Israel, in their endeavors to attract medical students into the field of pathology, and in the establishment of residency training programs," he said.

"I returned to the United States determined to help."

Dorfman contacted Dr. Ernest Rosenbaum, associate chief of medicine at Mt. Zion, and the two men organized a group of 15 physicians at Mt. Zion, Stanford, and at four medical centers in Israel to sponsor the fellowship.

First recipient of the fellowship is Dr. Eli Okon, who met Dorfman during his trip to Israel.

Okon is a senior lecturer in pathology at The Hebrew University—Hadassah Medical School in Jerusalem. He has done research at the Weizmann Institute of Science and was a fellow at St. Bartholomew's Hospital in London.

He was invited to come to Stanford last year by Dorfman, but limited finances prevented him from accepting until the fellowship was offered this spring.

Okon's fellowship is partially sponsored by donations given in memory of Sanford Haber, a former patient of Rosenbaum who "had a deep interest in Israel," Rosenbaum said.

-more-

In addition, Okon is relying on study benefit funding by Hadassah Medical School to support his three month stay in the U.S.

Okon said the fellowship money will help him cover part of his expenses and has enabled him to bring his wife and three children with him.

At Stanford, Okon will work primarily with Dorfman and his colleagues in the Surgical Pathology Department, reviewing over 100 pathology consultations per month, participating in interdepartmental conferences on the treatment of lymphomas (lymphoid tumors), and learning new techniques in immunopathology, the use of cell surface markers on biopsy materials to help make a diagnosis of cancer.

In addition, Okon will spend two weeks working in the clinical and tissue pathology labs at Mt. Zion under Drs. Frank Elevitch and Harvey Klein, and will have the opportunity to study the Hospital's applied computer technology.

He also will present a lecture on his own research in the field of neurohormones.

Dorfman said, "Following the remarkable efforts of Dr. Rosenbaum and his associates, I hope that sufficient funds may become available to allow us to establish this fellowship on a yearly basis."

With this in mind, he has asked several Israeli pathologists to form a committee to aid in the selection of a fellow each year.

In addition, the American Physicians Fellowship, Inc., for Medicine in Israel, has agreed to contribute toward the fellowship, he said.

The fellowship is sponsored at Stanford by Drs. Dorfman, Jerome Burke and Roger Warnke in the Department of Pathology, Department Chairman David Korn, Henry Kaplan, D'Ambrogio Professor of Radiology, and Dr. Stanley Schrier, head of the division of hematology.

Sponsors at Mt. Zion include Drs. Rosenbaum, Klein, Elevitch, Ben Coloff, Lawrence Feigenbaum, Alan Glassberg, and Bernard Kaufman, Jr.

Statement by Priscilla Wheeler for CRONA/Stanford University Hospital

(Wheeler is chief negotiator for the Hospital)

STANFORD—

Negotiating teams representing the Committee for the Recognition of Nursing Achievements (CRONA) and Stanford University Hospital announced July 6, 1980 that a tentative agreement for a new contract has been achieved.

The CRONA negotiating team has indicated that it will unanimously recommend the proposed agreement to the CRONA membership.

Details of the agreement are to be reported by CRONA to its membership with a ratification vote scheduled to be taken from Monday, July 7 at 3 p.m. until 6 p.m. Tuesday, July 8.

The agreement was hammered out by the two teams before Ruth Carpenter, mediator for the Federal Mediation and Conciliation Service in San Francisco.

Strike deadline for July 14 still remains in effect pending ratification of the agreement.

Dr. Lucien J. Rubinstein and his wife, Dr. Mary M. Herman will leave Stanford next year to join the faculty of the University of Virginia School of Medicine in Charlottesville.

Their appointments to the faculty will be effective in Spring, 1981, according to a University of Virginia announcement.

Dr. Rubinstein has been a professor of pathology at Stanford University School of Medicine since 1964. Dr. Herman has been on the Stanford faculty since 1966 and is an associate professor of pathology.

"They have outstanding international reputations as neuroscientists," said Dr. Norman J. Knorr, dean of the University of Virginia School of Medicine. "We look forward to their developing our neuropathology division and to the contributions they will make to our overall neuroscience research program."

Dr. Rubinstein has directed the neuropathology training program at Stanford and coordinated the neurobiology program at the Palo Alto Veterans Administration Medical Center between 1970 and 1974. He is an international authority on pathology and biology of nervous system tumors.

Dr. Herman's research has been primarily in neurooncology and neurodevelopment, and metabolic and age-related disorders of the central nervous system. In 1974 she won the Weil Award, given by the American Association of Neuropathologists, for the best paper in experimental neuropathology.

STANFORD—

Registered nurses at Stanford University Hospital have failed to ratify a new collective bargaining agreement.

The nurses, represented by the Committee for the Recognition of Nursing Achievements (CRONA) Thursday, July 3 began voting on whether to go out on strike, at 12:01 a.m. Tuesday, July 8.

The voting, which currently is taking place in the Medical School's Fairchild Auditorium, will continue until 6 p.m. Friday, July 4, "to make sure that everyone gets out to vote," said CRONA chief negotiator Joanna Nelson, R.N.

Over 700 nurses voted yesterday on the Hospital's proposed agreement, but failed "by a simple majority" to ratify it, Nelson said.

CRONA represents over 1,000 of the Hospital's nonsupervisory staff registered nurses.

Details of the vote and the tentative agreement have not been disclosed.

According to Priscilla Wheeler, chief negotiator for the Hospital, negotiations between Stanford and CRONA resulted in a tentative agreement on a new contract on July 1, in the presence of a federal mediator.

CRONA gave the Hospital a three-day extension of its original strike notice, which had set the strike deadline for midnight July 4, pending ratification of the agreement.

"My understanding is that the agreement fell short of ratification by a narrow margin," she said.

"The Hospital hopes that the CRONA membership will reevaluate its decision on the agreement."

Wheeler said reevaluation could include taking another vote on ratification.

She continued, "Because of uncertainties over the actual strike deadline provided by CRONA, the Hospital is exploring its legal rights to receive appropriate notice, under the health care amendments of the National Labor Relations Act."

Wheeler did not elaborate on what possible actions the Hospital may take.

"At this point, the Hospital's primary concern is to continue to provide for the welfare of its patients," she added.

According to Hospital Administrator Gary Mecklenburg, the Hospital will continue to curtail non-emergency admissions and elective surgery for patients who cannot be out of the Hospital by July 8.

Earlier, the nurses stated to the Hospital that they intend to provide coverage of critical care and other areas from which patients cannot be moved to other hospitals.

In addition, all admissions are now screened by the Emergency Department, and only critically ill patients who cannot be transferred to neighboring hospitals are being admitted.

Mecklenburg said that in the event of a strike the Hospital will reduce the number of patients from the average 500 to only 100.

Patients will receive instructions from their physicians of any changes in plans for their care. These may include transfer within the Hospital, or in some cases, transfers to neighboring hospitals.

In 1974 CRONA nurses walked off the job for 11 days. During that period supervisory RNs working with CRONA nurses under an agreement with administration, staffed the renal, coronary and intensive care units as well as the emergency and premature infants research center.

In 1978 last minute negotiations prevented a walk out scheduled for June 30 after a strike notice had been filed 10 days earlier.

STANFORD—

Even if a heart attack has been ruled out as the cause of your chest pain, it doesn't mean that you're free of risk.

A new Stanford study shows that patients hospitalized with chest pains and sent home after a heart attack has been ruled out, are more prone to having a serious or fatal heart attack than previously realized.

The study was conducted on 211 patients with chest pains admitted to the coronary care unit at Stanford University Hospital for evaluation of suspected heart attack, and carried out by Dr. John Schroeder, associate professor of medicine in the division of cardiology at Stanford University School of Medicine, and his associates Irene Lamb, R.N. and Marie Hu, M.A..

The researchers found that patients in whom a heart attack was ruled out were as likely to experience serious cardiovascular complications or death in the two years following hospitalization as were the patients in whom a heart attack was confirmed, according to a report in the July 3 issue of the *New England Journal of Medicine.*

According to Schroeder, the study identifies for the first time a group of high-risk cardiac patients who had not been previously recognized, and who need medical attention similar to that given patients who have had heart attacks.

"Normally, when we confirm that a patient has experienced a heart attack, there is a well defined course of treatment, and the patient receives careful monitoring and follow-up," Schroeder said.

"But when a patient comes in with chest pain and a heart attack is ruled out by the standard blood tests and electrocardiogram, the patient, family and doctor are all relieved, and the patient may go home and soon resume an active life without further follow-up.

"What we have found is that this is probably not appropriate, and these patients actually require similar surveillance and assessment as those who have had a heart attack," Schroeder explained.

Out of 211 admissions to the coronary care unit, 16 patients were found to have chest pains caused by conditions unrelated to heart disease. Among the remaining patients, 84 were found to have had a heart attack and six died in the hospital.

A heart attack was ruled out as the cause of chest pain in 89 patients.

The researchers followed the two groups of patients for 27 months following their discharge from the hospital. They found that the incidence of cardiovascular events (heart attack or death) was nearly identical in the two groups.

In those who had suffered a heart attack, 7.7 percent had another heart attack or died within six months of leaving the hospital, and 22 percent had a heart attack or died within 27 months of discharge.

But for those in whom a heart attack was ruled out as the cause of chest pains, 8.0 percent had a heart attack or died within six months, and 21.6 percent had a heart attack or died within the 27 month follow-up period.

The research was carried out with a grant from the National Institutes of Health.

STANFORD—

Registered nurses at Stanford University Hospital, represented by the Committee for the Recognition of Nursing Achievments (CRONA), have reached tentative agreement on a two-year contract with the Hospital, it was disclosed Tuesday, July 1.

The Hospital and CRONA jointly announced the tentative settlement, following seven weeks of negotiations.

Details of the agreement were not announced. CRONA gave the Hospital a three-day extension of the strike notice, pending ratification of the new contract by its membership Wednesday. CRONA represents more than 1,000 of the Hospital's non-supervisory staff nurses.

CRONA nurses last week gave the Hospital the required 10-day notice of their intention to strike unless an agreement could be reached by midnight July 4.

The current contract of CRONA expired Monday night.

The Hospital during the weekend took steps to curtail non-emergency admissions and elective surgery for patients who could not be out of the Hospital by July 4.

Hospital Administrator Gary Mecklenberg said today the Hospital will resume normal activities and admission with an affirmative vote on the new contract by the CRONA membership.

STANFORD—

Stanford University Hospital daily room rates will increase an average $32 in the fiscal year beginning September 1.

Medical, surgical and gynecology room rates will increase an average 15.5 percent from those set one year ago. These are the services that most hospitalized patients use.

The new rates, according to Executive Director Dr. Peter Levin, reflect the continuing impact of severe inflationary pressure on Hospital operating costs and salaries, a 50 percent increase in the cost of utilities, and a continuation of reduction in reimbursement from the government for care to Medicare and MediCal patients.

This year's increase is higher than last year's 11.6 percent, Levin noted. However, the Hospital's room rate increases for the past two years were below the rate of inflation for the same period, he added.

"This year's higher increase also indicates that the successful cost containment efforts of the past few years have limited the areas available for further reductions," Levin observed.

The new room rates were approved by the University after the Hospital's Board of Directors reviewed the annual budget on August 5, recommending rates for the new fiscal year.

The new rates will be $207 per day for ward accommodations, $223 for a semi-private room and $249 for a private room, an average increase of $32 from last year.

Medical, surgical and gynecology patients utilizing services of house staff physicians will pay $16 more than the above rates. The patient's attending physician determines whether such services are utilized.

Rates will increase an average 16 percent in some specialized units, including the intensive care and coronary care units, and the premature nursery.

Rates will increase 15.8 percent for obstetrics patients, 16.2 percent in the well-baby nurseries, 16.3 percent for psychiatry patients, and 16.0 percent for pediatrics patients.

Rates for x-ray, laboratory and other ancillary services will rise an average 16 percent.

The new room rates compare favorably with those charged by other similar highly specialized teaching facilities, Levin pointed out.

Patient revenues make up 99 percent of the Hospital's funds, according to Levin. The Hospital has neither tax support nor endowment income.

STANFORD—

Researchers in the department of pediatrics at Stanford University School of Medicine have discovered that it may be possible to decrease the severity of jaundice in certain infants by closely monitoring the diabetic woman during pregnancy.

Using techniques called "trace gas analysis," the researchers found an association between the amount of jaundice pigment produced in an infant of a diabetic mother and the degree of control of the mother's diabetes during pregnancy.

Dr. David Stevenson, assistant professor of pediatrics, explained that the new techniques enable them to measure infants' production of jaundice pigment by monitoring concentrations of expired gases in the breath of newborn babies.

Jaundice is a yellowing of the skin and other tissues, caused by deposits of bile pigment called bilirubin. If left untreated, it can cause other complications in the infants' health.

Stevenson and his colleagues, Clinton Ostrander, a researcher and development engineer, and Dr. John Johnson, now at the University of New Mexico, have been investigating the question of why jaundice occurs more often in prematurely born infants, infants of diabetic mothers, and in other infants with certain types of anemia, Stevenson explained.

Their findings have been published in papers in *The Journal of Pediatrics* and *Pediatrics* during the last year.

By measuring carbon monoxide (a byproduct of bilirubin production) in infants' breath, the researchers found that the infants have an unusually high production rate of bilirubin, a fact not previously known.

If the blood sugar of a diabetic mother is not carefully controlled during pregnancy, an increased amount of sugar passes to her fetus. The sugar stimulates increased production of insulin by the fetus' pancreas, causing the fetus to grow abnormally large.

"This abnormal large growth is also correlated with increase bilirubin production," Stevenson noted.

Another trace gas measured in the breath of infants is hydrogen, which is used by doctors to assess how well babies absorb their feedings, he added. Hydrogen is produced by bacteria in the intestines from carbohydrates which the baby has not absorbed.

"Feeding can be a major problem with prematurely born infants who often do not absorb milk sugars well," Stevenson said. A complicated and sometimes fatal disease called necrotizing enterocolitis is associated with poor food absorption, he added.

"Now, we may be able to determine which babies are at high risk for necrotizing enterocolitis, or to detect the condition before it becomes too serious," Stevenson said.

STANFORD—

They are theorists and dreamers who call themselves "knowledge engineers."

Linked by a sophisticated federally funded computer network across the country, these experts for the past 10 years have been laying the groundwork for tomorrow's thinking machines and how they might be adapted in medicine.

Their target: defining the laws of expertise so that they can be programmed into the computer.

How these experts work, their accomplishments, and future goals were the topic of a symposium on artificial intelligence recently held at the Stanford University School of Medicine.

"Artificial Intelligence is absolutely inevitable," declared Dr. Edward Feigenbaum as he discussed the emerging capabilities of computers to "think" with the use of specialized knowledge.

Such specialized knowledge is not contained in textbooks, he said. It is basically judgmental knowledge based on the rules of experience from working in a particular field.

He said it is the job of knowledge engineers to work with the experts to elicit this information, and to make it explicit so that it can be critiqued and a consensus reached.

Ultimately, according to Feigenbaum, an understanding of the nature of intelligence—whether expressed by man or machine—will lead to the design of computer-based tools that will aid doctors in becoming more effective thinkers and clinicians.

A key to this research is the SUMEX-AIM network directed by Feigenbaum. It stands for Stanford University Medical Experimental Computer-Artificial Intelligence in Medicine and is funded by the Division of Research Resources of the National Institutes of Health. It is within this computing resource that most programs using artifical intelligence have been developed.

But according to Feigenbaum, SUMEX-AIM system is more than that.

"It is the first electronically based scientific community," he said. "Nothing like it exists anywhere else."

The computers that drive the SUMEX-AIM system are much more powerful, providing sophisticated computation and memory capability for anyone who uses it. And it allows scientists to communicate rapidly with colleagues and to test their theories.

"When I am on sabbatical leave in Paris," said Feigenbaum, "I'll be able to communicate with my colleagues at Stanford on a daily basis."

There are scientists in more than 20 institutions in the United States and abroad using the system to tackle problems. One group is developing medical consultation systems. Another is investigating the use of artificial intelligence techniques in procedures of genetic engineering. Still another is tackling the more abstract issues of medical and scientific reasoning and theory formation.

-more-

But even with this concerted effort underway, the science of artifical intelligence in medicine is still very experimental, according to Harry Pople of the University of Pittsburgh. The consensus at the meeting was that at present no one program was ready for use by practicing physicians and that just when they will be ready is hard to predict.

Dr. Edward Shortliffe of Stanford said the programs were too large for most computers and too slow for most physicians, and that many fundamental questions about artificial intelligence still need to be answered.

Donald A. Lindberg of the University of Missouri added that we must yet program in "a sense of humility"—when the program doesn't know the answer, it must learn to say so.

Another problem with the existing programs is that each is limited in scope to a few diseases or disorders. (INTERNIST, a program being designed to serve as a consultant for doctors of internal medicine, is the exception with almost 500 diseases in its knowledge bank.)

But the scientists hope to eventually distill the essence of expertise so that the same programs can be used for consultations on other diseases.

Even if the programs are perfected the knowledge engineers realize that the programs must be attractive and believable to physicians. Therefore, a substantial part of their research is focused on making the programs palatable to the physician. Having it explain its actions and respond to questions rather than just spewing out an answer are two of the human qualities that the scientists are trying to engineer into the program.

"Artifical Intelligence will make for good medicine," Lindberg said. Doctors won't be replaced by computers, he continued, only helped.

STANFORD—

Dr. Lawrence G. Crowley has been appointed vice president for medical affairs at Stanford University, effective immediately.

The appointment, culminating a nationwide search by a faculty committee was announced Tuesday, Aug. 19, by President Donald Kennedy.

Crowley served as acting vice president and dean at the Medical Center for the past 20 months.

"Stanford is fortunate that Larry Crowley has agreed to continue his thoughtful, effective leadership of the Medical Center," Kennedy said.

"I look forward to continuing the strong working relationship that has already grown between us."

Kennedy added that even under the handicap of acting status, Crowley "has been able to work effectively with the faculty, both developing concensus about the Center's future and in making progress toward it."

He said these qualities of conscientious consultation and strong administration are exactly what is needed to help the Medical School's faculty fulfill its own extraordinary promise and to guarantee another period of progress in research, medical education, and patient care.

"The extensive search for leadership that was in the process during this entire period enabled us to conclude with confidence that the best person for the job was the one who was already doing it so well."

Crowley's appointment marks the first time that the posts of vice president for medical affairs and dean of the School of Medicine will be separate.

His predecessor Dr. Clayton Rich who resigned in 1978 held both positions.

Crowley, who will remain acting dean, said he would begin a search for a dean promptly.

He said he regards his appointment as a great challenge and opportunity and looks forward to working with the faculty and university administration in the next four years.

"The Medical School must preserve its strong research program thrust, and the Hospital should continue its provision of a strongly supportive environment for clinical research," he said.

Crowley who is 61 was born in Newark, New Jersey. He is a graduate of Yale University (1941), and of the Yale University School of Medicine (1944).

He was a professor of surgery at Stanford from 1964 to 1974. He became dean of the University of Wisconsin in Madison that year, but he returned to Stanford in 1977 as professor and deputy dean.

Prior to coming to Stanford, he had served on the faculties of Yale and the Universty of Southern California.

He also served as chief of surgery in Stanford's affiliated Palo Alto Veterans Medical Center, and was responsible for the publication of the Comprehensive Stanford Medical School long range academic plan when he served as associate dean in 1972-74.

STANFORD—

While working in an Alaskan crab packing plant, Alfredo Domingo caught his shoulder-length hair in one of the machines, ripping the scalp off his head.

The accident occurred on August 4 and the 21-year-old Domingo was rushed to a nearby Anchorage hospital, then flown overnight to Stanford University Hospital for surgery, arriving early the next morning. With him on that flight—packed in a bucket of ice—was his scalp.

It was Domingo's fellow workers at the plant who apparently thought to keep the scalp cool. And because of that prompt action, the scalp tissues stayed alive, enabling Stanford surgeons to reattach the scalp more than 24 hours later.

"What is unusual," says Dr. Vincent Hentz, assistant professor of surgery at Stanford Medical School and chief of plastic surgery at the Palo Alto Veterans Administration Medical Center, "is the great delay between when the scalp was torn off and putting it back on successfully.

"Fingers have been put back on days later because the tissues, if cooled, don't require much of a blood supply. But I don't believe such a delay in reattaching a scalp has been reported."

By using microsurgery, which involves working under magnification with extremely small tools and sutures one-fifth the thickness of a human hair, Hentz and a team of four plastic surgery residents worked nearly 11 hours to save the Stockton youth's scalp.

The vessels were torn and stretched so badly, says Hentz, that the arteries and veins attached to the scalp could not be directly sutured to the arteries and veins in the patient's head and face.

So the surgical team took veins from Domingo's foot to bridge the gap between the damaged vessels and those in his head and face, much the way a pipefitter would fit a pipe.

During the operation, which began at 8 A.M. and ended around 6 that evening, Domingo received 9 or 10 units of blood, which is almost enough to replace the body's entire blood supply.

Had his scalp died, says Hentz, he would have had to undergo a number of reconstructive operations, since the accident left 60% of his skull exposed and bare bone won't accept skin grafts.

And although it is possible the scalp still could die, it has been almost two weeks since the operation and Hentz is confident the patient is well on the way to recovery.

"It's conceivable," he says, "that he could go back to work in four weeks."

Hentz estimates the overall cost of Domingo's hospital stay at between $10,000 and $15,000, which should be picked up under his insurance policy with the company. If reattachment had failed, says Hentz, medical costs could have been as high as $50,000.

STANFORD—

On a recent Tuesday, JoAnn Hattner made the rounds of the obstetrics and gynecology clinic at Stanford University Hospital as she always does. A less stalwart soul might have found the first encounter discouraging enough to quit for the day.

"I'm not hungry," the woman told Hattner, angered by all the questions. "I just don't like any of them foods...so how do you expect me to eat them?"

In her fourth month of pregnancy, the woman was considered high risk because of known alcohol abuse. It was Hattner's task to determine why she had lost two pounds in the last month and how to improve her diet enough to ensure a healthy weight gain - and more importantly - a healthy baby.

Nutritionists like Hattner are pretty much in agreement that the ideal weight gain for a pregnant woman of normal weight is 24 pounds during a 40-week gestation period.

But this was one battle in the field of preventive nutrition that Hattner seemed likely to lose. Whatever she suggested met with resistance.

In Hattner's work, however, this is the extreme case - not the norm. For the rare patient whose attitude prevents meaningful counseling, there are dozens who respond positively to nutritional advice.

A registered dietician, Hattner serves as a consultant on nutrition to three medical specialties - obstetrics, neonatology and pediatrics. Her services are contracted out through the Department of Dietetics to the Hospital and the Children's Hospital at Stanford.

Over the past nine years at Stanford, she has carved out a specialty in the area of preventive nutrition for pregnant women and infants through childhood. When preventive measures fail prenatally, she provides therapeutic nutrition.

She readily admits that she prefers this to working with sick adults whose bad eating habits often contribute to their illness.

"I don't think I have the tolerance for adults who continue to abuse themselves nutritionally," she says. "It's possible to influence a child's nutrition through the mother... and for me, at least, this is far more rewarding.

"I strongly believe that nutrition - prenatally, in infancy and childhood may well be the key that affects the quality of health for an individual."

In recent years, Hattner has received considerable attention in the press, partly because she is such an articulate spokeswoman and partly because of a renewed interest in nutritional issues.

-more-

She has often been quoted as saying the best time to reach a pregnant woman is before conception. And this is still one of her strongest convictions.

"We really should be preparing women better for pregnancy, she says, "and before they get pregnant is the best time for a woman to come to an ideal weight and establish good nutritional habits."

In July Hattner addressed educators, nurses, and other health professionals at a conference in Las Vegas on prevention of developmental disabilities. It is her hope that the meeting will result in more nutrition programs for high school girls.

Her own interest in nutrition apparently goes back to her childhood, which was spent largely on hospital grounds. Her father, now retired, was a psychiatrist and administrator for the Veterans Administration and he encouraged her to go into the profession of dietetics.

Historically, according to Hattner, nutrition grew out of home ecnomics, a field traditionally dominated by women. And even today, she says there are far more women in nutrition than men.

Hattner received her B.S. degree from the University of Idaho in 1963, then went to the University of California Medical Center in San Francisco for a fifth year internship in dietetics.

Shortly after graduation, she came to work at Stanford. She took time out in 1967 to earn a masters degree in public health at Berkeley, then worked in public health and clinical research before returning to Stanford.

Although much of nutrition is common sense, she says, clinical studies are difficult to run because of the legal and ethical complications involved.

"You can't take two pregnant mothers and feed one alcohol just to study the effects," she says. "So the work is done strictly by observation and pregnancy outcome...meaning, of course, the infant."

One of the studies Hattner is currently involved in concerns the feeding regimens of the premature infant.

The study, which ends next year, is funded under a three-year federal grant and is being carried out by the Department of Pediatrics. Some of its findings were reported recently at the department's conference on nutritional care of the high-risk pregnant mother and that of the immature or ill infant.

"One of my roles," says Hattner, "is anthropoemetric measures. What this means is I'm essentially looking at body composition as a means of assessing growth."

Body composition is determined by measuring an infant's arm circumference and, through the use of calipers measuring skin folds of subcutaneous fat. Although length, height and weight are also taken into account, body composition is an important component in evaluating infant growth.

Hattner says this method was also used in another study, looking at infants of mothers with diabetes and gestational diabetes. That study, which combined the work of neonatology, hematology and nutrition, found that babies of diabetic mothers do have increased fat.

Research apparently takes up roughly 20 percent of Hattner's time. On Wednesdays through Fridays, she sees patients at the Hospital or at Children's Hospital. Many of them are high-risk.

-more-

No matter what the nutritional problem, Hattner works closely with physicians in designing a therapeutic regimen for each patient. She also works, in many cases, with a social worker to determine environmental factors that might affect diet.

In the genetic metabolics clinic at Children's, Hattner deals with infants up through childhood who have an inborn error in their metabolism, such as PKU (phenylketonuria). Through special formulas, which restrict the amino acid that causes brain damage, treatment of PKU over the past 15 years has met with increasing success.

"The new challenge in the area of preventive nutrition," says Hattner, "is to find ways of treating young women who have PKU."

Other clinics where Hattner takes her nutritional expertise include gastroenterology and endocrinology. Because many of the babies and children she sees are failing to thrive, she must deal not only with their problems, but with the emotional strain on the parents.

"There is a tremendous amount of guilt involved," she says, "because the thinking is, 'surely, a mother should be able to nourish her own child'."

At the hospital, Hattner's chief responsibility is the implementation of a quality assurance program for patients. The program, she says, came about as a result of her three-year chairmanship of quality assurance for the California Dietetics Association, which has 4000 members.

"I think we're the forerunners in California to define certain nutritional guidelines," she says. These guidelines include assessing a patient's needs according to the length of stay and priority from a medical standpoint.

A patient, who has had open heart surgery, for instance, will have a greater need for nutritional therapy than one who is in the hospital for minor surgery.

"The hope," says Hattner, "is every patient who comes into the hospital will be nutritionally assessed.

CITY EDITORS: This is the first of a two-part series.

STANFORD—

In the past month Stanford University Hospital has hired some 50 registered nurses to ease its current nursing shortage, although many of those hired are recent nursing school graduates who must be trained first before they can work on the floor.

"When you talk about shortages," says Nancy Madsen, associate director of nursing services,"you have to look at functional nurses...those who are working right now and have enough training to work in an acute care setting such as this one."

Although not nearly as severe as the national problem, the Hospital's present vacancy rate is high enough to cause concern—at least until October when the new hires have completed their orientation and staffing is back to normal.

Madsen says the Hospital is attempting to close out 20 patient beds in the Main Center during this interim period.

At the moment, the most acute staffing shortages exist in Stanford's five medical units and one pediatric unit.According to Madsen, there are 40 full-time equivalent vacant out of 152 full-time positions in this unit. These numbers, however, are deceptive since nearly three-fourths of the Hospital's RN staff work less than 100 percent, which means it usually takes two nurses to fill one post

"Nurses today," says Madsen, "are becoming as specialized as physicians , so the immediate problem can't be solved by simply shifting nurses around. We have to look at units with similar care needs."

Nationally, hospital administrators now face a nursing shortage of 100,000 and an alarming drop-out or burn-out of 30 to 40%. In addition, an estimated 40% of the nation's 1.4 million registered nurses now work four days a week or less.

As a result, recruitment efforts have expanded dramatically in recent years. At Stanford, hospital administrators feel their task should be easier now that CRONA (Committee for the Recognition of Nursing Achievements) has ratified a new 20-month contract, making Stanford's salaries more competitive with other Bay Area hospitals.

"The new contract has lareay helped with our recruitment efforts," says Katie Bray, coordinator of nurse recruitment and retention at the Hospital.

-more-

"Having a competitive salary is very important if you don't want nurses bouncing around from hospital to hospital for a nickel an hour increase."

In the past, Stanford fell behind in salary negotiations because of earlier contract expiration dates elsewhere. The new contract, which Bray describes as" one of the finest packages on the West Coast", will bring the Hospital more in line with other facilities , although there still will be a three-month time lag.

Ratified by CRONA members on July 8, the new contract went into effect, July 1 , and expires in February of 1982. CRONA is the professional organization that represents the Hospital's 1000 non-supervisory registered nurses.

The contract calls for an immediate 12% salary hike this year, a 3% increase on March 1, 1981 and a 9% increase on July 1, 1981. It also provides for an increase in the night shift differential from 12 to 14 % and improvements in educational and retirement benefits.

For experienced nurses in the top classification, the salaries are apparently the highest in the Bay Area.

Since last year, according to Bray, Stanford has cut its vacancy rate for nurses in half through the active recruitment efforts of Administration, Personnel and nurses and doctors.

"I think this is a very unusual effort," she says."There are many hospitals where nursing doesn't know what personnel is doing and vice versa.

"The profession has become highly pressured, highly technical," says Bray, who was recently elected president of the San Francisco Bay Area Association of Nurse Recruiters. "It has the same kind of curve as medicine in general.

"And in a hospital like Stanford where you find very complex research going on in cancer and heart problems, the knowledge of the person who takes care of the patient must also increase."

The resulting stress, adds Bray, means more and more nurses have cut back on their hours or quit the profession altogether.

The nursing profession has also lost numbers in the last decade because of new professional opportunities that have opened up for women. Many women, who once went to nursing school, now go on to medical school instead.

This national shift in emphasis was reflected on Stanford's own grounds five years ago when the decision was made to shut down its nursing school because of competition with the Medical School over available funds.

"That decision hurt us in two ways,"says Duane Walker, director of nursing services. "It took away a natural pool of trained nurses and it discouraged nurses who wanted to go on for bachelors or masters degrees from doing so. When they found it was not available here, they went elsewhere."

Walker says one of the highlights, or "most glamourous changes" in the new contract are the educational benefits. Nurses who want to go back to school can now receive up to $1000 in reimbursement costs.

"I'm not aware of many hospitals who are doing that," he says, adding that prior benefits only provided small stipends for workshop or seminar costs and tuition reimbursement.

By September,1982, according to Walker, working nurses at Stanford will be able to study under a satellite program set up by San Jose State on Hospital grounds. The program, he says, has already received federal funding.

Walker sees this venture as a recruitment attraction. Other measures the Hospital has undertaken to attract nurses includes the provision of temporary housing for out-of-state nurses. Nurses now can lease an apartment for up to three months before having to find housing of their own.

"Before the Hospital decided to do this," says Walker, "we actually found three nurses living in the back of a Volkswagon van, trying to save up enough money for a deposit on a place of their own."

Like Bray, Walker emphasizes the joint efforty of Hospital personnel in recruiting new nurses. Stanford advertises in national journals, holds open houses and sends recruiters to nursing job fairs around the country. "We're getting our own staff to be ambassadors," he says. "And right now we are looking at the system with an eye to providing monetary incentives for bringing in new nurses."

Equally important, however, is the retention of the nurses already working at Stanford.

Throughout negotiations, CRONA members voiced the need to address the problems caused by nursing shortages. The main concern is added stress in a job already filled with stress.

"I hope the new contrract will have a positive effect on these problems," says Joanna Nelson, R.N., president of CRONA. "Women are beginning yto look ahead a bit more. . .to built-in incentives for them to stay in the nursing profession."

As for the current contract, Nelson calls it "very competitive right now." Whether it remains so, she says, depends on what other Bay area hospitals do when their contracts are negotriated.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR FURTHER INFORMATION CONTACT: Susan Jenks 415-497-6911

STANFORD—

CITY EDITORS: This is the second of two parts.

In the intensive care unit a young woman lies curled up in pain, her only movement an involuntary twitching. Unit nurses take turns monitoring "drips" or solutions round-the-clock as they have for nearly three months, although there is still no sign of improvement in the patient's condition.

Laurie Gunderson glances quickly at the woman, then shakes her head. As the clinical nurse coordinator for the Hospital's 25-bed cardiovascular ICU, she has seen many critically ill patients who linger on indefinitely with no improvement.

"The nature of this unit," she says, " is mostly life and death situations that are stressful. But this kind of patient—who after months of care shows no improvement—is perhaps the most stressful."

The issue of nursing stress has only recently gained momentum as hospital administrators across the country face a nursing shortage of 100,000 and an alarming 30 to 40% drop-out or burn-out rate of those in the profession. In addition, an estimated 40% of the nation's 1.4 million registered nurses now work four days a week or less.

At Stanford, the statistics are perhaps less dramatic, but the problems are not. An acute care institution, which serves as a teaching hospital and a community referral center, Stanford nurses apparently experience greater stress than the average nursing population.

Although research on work-related stress of nurses is still in its infancy, a recent study of 1800 ICU nurses by the University of California's School of Nursing, San Francisco (UCSF), concluded that this was particularly true for Stanford ICU nurses because of the Hospital's international reputation in heart transplant work and "other complex and specialized surgical and medical interventions."

Stanford was chosen as the demonstration site in the local area because it has three ICU units—cardiovascular, surgical and medical—and employs the largest number of ICU nurses in the Bay Area.

ICU nurses were extracted from the general nursing population because of considerably higher turnover rates. An estimated 51% of the nation' hospitals currently show severe shortages in their intensive care units.

But whether or not ICU nursing is actually more stressful than other types of nursing is a subject of controversy. And to date, there have been no studies comparing nursing stress.

"Each unit has its own type of stress," contends Joanna Nelson, an R.N. and president of CRONA (Committee for the Recognition of Nursing Achievements), the union which represents the Hospital's 1000 non-supervisory nurses. "ICU nurses say they have higher stress. . . those of us on the floor say that's highly debatable."

Nelson apparently found her own work at Hoover Pavilion so stressful that she cut back to four days a week.

"My patients were so ill," she says, " that I began to have bad dreams and I couldn't sleep at night. Many nurses handle stress the way I did by cutting back to a shorter work week."

In Stanford's nursing population, nearly three-fourths of the RNs work less than 100 percent, which means it usually takes two nurses to fill one full-time vacancy. Administrators have stepped up recruitment tactics dramatically in recent years, although staff shortages are a chronic concern. Fewer nurses obviously means more stress for those left on the floor.

"If there aren't enough nurses," says Tricia Dotti, a staff nurse on East 1A, "you can't give the kind of care you want to give and this is very frustrating."

A general medical unit with 34 beds, East 1A, has had unusually high staff shortages in recent weeks. According to Anna Olson, the clinical nurse coordinator for the unit, East 1A is budgeted for 22 full-time nursing positions, but only 14 of these are filled right now. And since all but two nurses on the unit are part-time, this means it is operating with 16 fewer nurses than usual. - more -

2-2-2 Olson sees the major factor in today's nursing market as the shift of nurses away from hospital work to registries, or private companies.

"This allows a nurse," she says, " to choose not only where, but when she'll work and for more pay."

Other sources of stress on East 1A are typical in other units as well. Nancy Madsen, associate director of nursing services, describes one such problem as the "pure crunch of physicians."

On Olson's floor there are four medical teams—three teaching teams and one community team—and each of these teams has six to eight physicians. Not only does this result in an inevitable overlap of medical opinion, but there is a space squeeze as well.

"You have to be an excellent communicator just to know who to talk to around here," says Myrna MacAllister, the unit's assistant clinical coordinator. That problem is apparently compounded when nurses have to deal with overworked physicians who have been up all night.

"Their pressure definitely filters down to us," says MacAllister.

In the University of California study, staff shortages and "personality conflicts" with staff, physicians, administrators and residents were identified as the leading stress factors for Stanford's ICU nurses.

North ICU, where Gunderson works, is currently operating with 19-20 nurses per shift, although normally there are at least 23 on a shift. Unlike a general nursing unit, however, where nurses must take on an additional patient load, ICU nurses always provide one on one care.

"An RN has to be in every room because of the acuity of our patients," says Gunderson. "This means when there's a shortage, we can't stretch our staff. If there aren't enough nurses, we have to close down patient beds."

To meet current shortages, Gunderson says, non-ICU nurses are being trained for the first time with the help of Hospital inservice instructors. That training will include a high degree of technical expertise since ICU nurses must operate a staggering number of machines.

Although this is challenging, says Gunderson, it is one of the reasons she feels ICU nursing is more stressful than working on the general floor.

Elle Hedenkemp, an ICU nurse for the past six years, agrees that ICU nursing is more stressful—at least in some ways.

"There are more dramatic situations here. . . with families totally out of control," she says, "but those of us who choose this kind of work are a funny breed who thrive on the challenge.

"I found it very frustrating out on the floor because it's harder to have an in-depth relationship with a patient. Here there is a lot more feedback from patients and their families and that is very gratifying."

Whatever the stress source, Anne Baldwin's job is to identify it, then find ways of alleviating the stress before "burn out" occurs. Baldwin was hired by the Hospital four months ago as its first nurse coordinator of a nursing consultation program.

The supervisory position, according to Duane Walker, director of nursing services, was created as a result of the UCSF findings.

"We were definitely responding to this study," he says.

Baldwin describes the purpose of her job as providing consultation to any nursing unit that would like help with work stress. Her background includes 12 years of nursing experience and a doctorate from the University of Michigan in educational psychology.

"My belief is all nursing jobs are too stressful," she says. "In fact, they are so stressful that they are incompatible with adult living and personal and professional growth."

One of the biggest psychological issues in nursing today, says Baldwin, is the loss of patients. Often times they—not the doctor—are the instrument of pain.

"To last very long in this profession," contends Baldwin, "nurses must learn to grieve, then go and form other attachments."

Baldwin's advise to the individual nurse suffering from stress is to "talk it out, think it out, exercise it out."

As for the Hospital's role, she says, it must provide good listening channels, regular support groups and educational programs for nurses on the nature of stress.

STANFORD—

A record 26 percent of this year's incoming class at Stanford University School of Medicine is composed of minority students, and 36 percent of all entering students are women.

Among 86 matriculants there are 13 chicanos, six blacks, two native Americans and one Puerto Rican. Thirty one incoming students are women.

According to Director of Admissions Dr. Laurence Kedes, Stanford Medical School has the highest minority enrollment figures and has recently ranked second in enrollment of women among 13 private medical schools that form a medical school consortium. (The consortium schools form a cooperative group, sharing information in areas of common interest. Members include Case Western Reserve, University of Chicago, Cornell, Duke, Harvard, Johns Hopkins, Columbia, University of Pennsylvania, University of Pittsburgh, University of Rochester, Washington University and Yale.)

Last year, a study of minority admissions published in the *New Physician* magazine ranked Stanford fourth in performance among 121 medical schools in the area of minority admissions. (The study excluded medical schools that are predominantly black.)

Stanford Medical School has been particularly successful in attracting highly qualified chicanos, noted Dr. John Steward, associate dean of student affairs. "Being on the West Coast, we feel a strong obligation to chicano applicants, and we find many choose Stanford because of the proximity to major centers of chicano populations," Steward said.

Kedes noted there is concern that numbers of black students applying to medical schools have leveled off after a sharp rise that began in the early 1970's. Competition among medical schools in recruiting qualified black applicants has accordingly increased, he added.

"The competition for black medical students is stiff," he said. "Every one of the black applicants we accepted this year had also been accepted by several other top medical schools."

As a result, although Stanford Medical School offered places in its first year class to 23 blacks, only six actually matriculated, he observed.

"Black students may prefer medical schools in urban centers with higher black populations," Steward suggested as one explanation for Stanford's high turn-down rate from blacks this year.

-more-

In contrast, 13 out of 19 Chicanos accepted this year are attending Stanford, two out of three accepted Native Americans are enrolling, and the single Puerto Rican accepted has decided to attend Stanford, Kedes added.

About 50 percent of the incoming students intend to pursue careers in academic medicine involving research in basic or clinical sciences, Kedes said, while 35 percent of the students plan to practice medicine outside an academic affiliation. The remainder (15 percent) is undecided on career goals.

The Medical School faculty senate recently approved, in principle, a three-part curriculum encompassing basic medical science, clinical medicine and investigative medicine. The addition of the third component, investigative medicine, "embodies what is special about the School and its avowed mission to train all our students for leadership in the practice of scientific medicine," said Dr. Avram Goldstein, senate chairman and professor of pharmacology.

Goldstein noted that Stanford feels an obligation to identify and attract minority students who are committed to academic careers in order to help alleviate the shortage of minority faculty members in medical schools.

In addressing the incoming class September 22, during orientation week, Goldstein said, "Women and minorities are, as you know, very much underrepresented in the medical profession. This imbalance is far worse in academic medicine. If you see so few role models among the professors at this (or any other) medical school, that very fact is indicative of the need.

"Careers in academic medicine are enormously rewarding, and they are very much open to you. Maybe an academic career is right for you, and you haven't yet considered it one of your options. Find out more. The faculty will be ready and eager to help you."

Goldstein continued, "This faculty admires, appreciates, and rewards the inquiring minds among you. This faculty is here because Stanford is one of the world's great centers for research in medicine and biomedical science. Through research and around research we have created an environment here in which you can learn. And we are stimulated by the challenge of inspiring bright young minds to follow our path and to surpass what we have accomplished.

"This devotion to research is part and parcel of our concern for patients . . . and beyond the welfare of our own patients, in a wider context, medical research is the sure hope of the future, for the prevention, cure, and alleviation of disease, and eventually for an improved quality of life for the entire human race."

STANFORD—

Paul Berg, Ph.D., of Stanford University School of Medicine, will be awarded $15,000 for his contributions to science, the Canadian-based Gairdner Foundation announced Monday in Toronto.

Berg, Willson professor of biochemistry, will be one of six scientists from Canada, the United States, and Israel, receiving individual awards.

He will receive the award "in recognition of his contributions to our understanding of the mechanisms of protein synthesis and of the interplay of viral and cellular genes in regulating growth and division," the foundation said.

Berg has devised new and physical approaches to analyzing the structure of simple viral chromosomes, making possible a molecular approach to the study of their genetics.

In addition he and his colleagues have been active in the development of recombinant DNA techniques to introduce new genetic information into mammalian cells with virus DNA vectors.

These experiments are designed to explore the chemistry and biology of mammalian and human chromosomes and hopefully to provide the basic knowledge for the prevention, management and cure of hereditary diseases.

The awards will be presented October 16 and 17 at the 1980 Gairdner Foundation Lectures at the University of Toronto.

This year's winners were selected from more than 117 nominees by the foundation's medical advisory board, chaired by Dr. C. H. Hollenberg, foundation president and chairman of the University of Toronto's department of medicine.

The other winners are Irving B. Fritz, University of Toronto; H. Gobind Khorana, Massachusetts Institute of Technology; Efraim Racker, Cornell University; Jesse Roth, National Institutes of Health; and Michael Sela, Weismannn Institute of Science, Israel.

The Gairdner Foundation was formed in 1957 by the late James A. Gairdner and his family in Toronto to recognize outstanding contributions to medicine.

STANFORD—

Dr. Avram Goldstein, professor of pharmacology in the Stanford University School of Medicine, has been re-elected for a second term as chairman of the School's faculty senate.

Also re-elected is Dr. Frances K. Conley, assistant professor of neurosurgery.

Three new members were elected to serve on the committee of five of the senate for 1980-81. They are Drs. Roy H. Maffly, professor of medicine; Lars M. Vistnes, associate professor of surgery; and Irving L. Weissman, associate professor of pathology.

Weissman, former chairman of the senate, had served as an ex-officio member of the committee last year.

Goldstein's re-election was interpreted as a vote of confidence to the movement of change that he and other faculty members were responsible for instigating in the Medical School.

During the past year the senate approved in principle a three-part curriculum in basic medical science, clinical medicine and investigative medicine. The action was taken to serve notice for prospective students, faculty, and other interested individuals that Stanford's curriculum has a two-fold purpose:

That purpose is "to develop in all students the capacity for leadership in the clinical practice of scientific medicine, and to provide opportunities for as many students as possible to prepare themselves for careers in research and teaching in the various branches of basic, clinical, and social medicine."

The committee of five is the executive board of the faculty senate. The senate represents the School's faculty, defines admission and graduation requirements as well as curriculum and academic policy.

FOR IMMEDIATE RELEASE

STANFORD—

Dr. Norman E. Shumway, Stanford University's heart transplant pioneer, Thursday (Sept. 25) became a Fellow of the Royal College of Surgeons in Manchester, England.

The 56-year-old Shumway is the first contemporary Stanford surgeon to be so honored by the prestigious College.

In England Shumway also gave the Moynihan Lecture, honoring the late Lord Berkeley Moynihan, a famed surgeon and the College's first president.

Shumway discussed the clinical status of heat transplants. One-year survival rates for transplant patients have climbed from 22 percent in the first year to a peak of 70 percent in 1980, he said. About half of those who receive a donor heart today can expect an additional five years of life.

His research team has transplanted 213 hearts into 195 patients in the past 12 years. Of these 77 are living—one patient for more than 10 years. (The discrepancy in figures is due to the fact that some patients had more than one transplantation).

"This improvement in survival," said Shumway, "comes not as a result of some fantastic breakthrough, such as specific induced tolerance (though such an event is probably inevitable), but rather from judicious adaptation to patients of techniques developed in the experimental laboratory."

FOR IMMEDIATE RELEASE

STANFORD—

Fifteen junior faculty members at Stanford Medical School who are cancer researchers have been appointed Agnes Axtell Moule Fellows for the current academic year.

The appointments were announced by Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean at the medical school.

The fellows are Drs. Barbara Carroll, C. Norman Coleman, Peter Fessenden, Richard T. Hoppe, Alvaro Martinez, and Anthony E. Howes of the Department of Radiology; Drs. Jerome S. Burke and Roger A. Warnke of the Department of Pharmacology; Dr. Laurence J. Korn of the Department of Genetics; Dr. Branimir Sikic of the Department of Medicine; Dr. Ann M. Arvin of the Department of Pediatrics; Dr. Peter Parham of the Department of Structural Biology; and Dr. Robert Kessler of the Department of Surgery.

The fellowships are administered by the Moule Medical Research Foundation, which was established by Manley A. Moule as a memorial to his mother who died of cancer in Palo Alto in 1939. The fellowships provide, in addition to some salary support, $1,000 for laboratory or teaching expenses and $500 for travel to scientific meetings.

Moule, a 1917 graduate of Stanford, was associated with the W. Ross Campbell Co., a real estate firm in Los Angeles. Mrs. Laleah Moule continues to live in the home Moule built in San Marino, CA, 50 years ago.

STANFORD—

Four junior faculty members at Stanford Medical School have been appointed William H. Hume Faculty Scholars for the 1980-81 academic year.

They are Dr. Eric. I Knudsen of the Department of Neurobiology, Dr. Bruce R. Ransom of the Department of Neurology, Dr. Stephen J. Shochat of the Department of Surgery and Dr. Douglas C. Wallace of the Department of Genetics.

The fellowships provide, in addition to some salary support, $1,000 for laboratory or teaching expenses and $500 for travel to scientific meetings. They are funded from the $5.6 million gift left to Stanford School of Medicine by the late William Mansur Hume of Woodside and San Francisco.

A native of Indiana, Mr. Hume was the founder of Basic Vegetable Products, Inc. He served as president, chairman and director of the San Francisco based firm.

As stipulated in Mr. Hume's will, all the fellows are engaged in basic biomedical research.

* * * * *

Knudsen is studying how sound is pinpointed. Using the owl, an animal particularly good at locating sound, he is observing its behavior when sound is beamed its way. He is also monitoring the biomedical changes taking place in the nerve cells in the various brain pathways involved in hearing.

Dr. Shochat is monitoring the immune system in children with solid tumors. He is also studying the effects of anesthesia on the immune system.

How their environment influences the functioning of the two major types of cells in the brain, neurons and glial cells, is the research interest of Ransom. He is exploring how the ion, potassium, affects their membrane potential and if neurotransmitters, chemical agents used by nerve cells to communicate with one another, can act on the glial cells.

Wallace is studying the genetics of the DNA in the cell's powerhouse, the mitochondrion. Only a small amount of DNA, the cell's hereditary material, is found in mitochondria; the majority is found in the cell nucleus. Wallace has identified genetic markers in the mitochondria of human blood cells through which he learned that mitochondrial DNA comes solely from the mother. The DNA found in the nucleus is half from the father and half from the mother.

The appointments were announced by Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean of the medical school.

STANFORD—

If deaf patients want to say, "Help me!" in sign language, chances are they won't be heard. Most doctors and health professionals aren't trained in sign language.

While an interpreter is often the answer, a doctor's familiarity with sign language can avoid misunderstanding and frustration, and can be critical—especially in emergencies.

Responding to this need and to state and federal requirements for the disabled, Stanford University Hospital is training both Hospital and University employees in American Sign Language (ASL), the native language of most deaf adults in the U.S. today.

In the past the need for interpreters at the Hospital was met by an occasional staffer who knew the language, students recruited by the Social Services Department, or deaf patients who brought their own interpreters.

The ASL course is sponsored by the Hospital's Human Resources Development Department. "One of the goals," says Nina Gelfant, the instructor, "is to provide the Hospital with skilled signers on the staff."

As a result of last year's classes, she says, several staff members now use ASL well in their areas of specialization.

Gelfant hopes to improve the program by inviting more deaf people to participate in class sessions. "Human contact is essential," she says. "ASL cannot be learned alone at home or from a book."

And she hopes to continue the course beyond the initial term, because she feels that 10 weeks is not enough time to attain proficiency in signing—only enough for a good start.

Even if physicians know just a touch of ASL, Gelfant says, the psychological boost they'll give their patients can help in the total healing process.

Unfortunately, last year the course failed to attract physicians. One reason, says Donald Thomas, director of Hospital Personnel, is that physicians are hard-pressed to find the time. To fit individual schedules, a program using videotape cassettes is under consideration.

It is important to understand, says Gelfant, that ASL is not a strict visual representation of English, as is "Signing Exact English," a new sign system being used in some schools.

"This is a moving, growing, expressive language with its own grammar and usage," she says of ASL. "And it's a physical language.

"To communicate effectively with most deaf Americans, one must learn ASL."

Although not deaf herself, Gelfant emphasizes that there is a cultural perspective to learn along with the language, since ASL does not contain many of our common idioms. For example, she says, Stevie Wonder's popular lyric, "You are the Apple of my Eye," would be a mystery in ASL.

Also, says Gelfant, the deaf may not understand how different aspects of their lives, such as marital relationships, relate to questions of health. Therefore, physicians may need to explain more thoroughly why such questions are asked.

Gelfant is the interpreter coordinator of the Deaf Counseling Referral and Advocacy Agency in San Jose. She teaches in the interpreter training program at Ohlone College and in the Linguistics Department at Stanford.

STANFORD—

Old people go crazy for three reasons, according to Dr. Alex Comfort, noted English researcher on aging and author of many books, including the best-seller, "The Joy of Sex". They've been crazy their whole lives. They get ill and go crazy. Or we, as a society, drive them crazy.

It is the later reason, the "sociogenics" of aging that Comfort singles out as the most heinous culprit of all in society's demoralization of the elderly. Myths about little old ladies in tennis shoes or old gents who are "bonkers", says Comfort, are far more damaging than the physical realities of aging.

"We now know that intelligence does not decline with age, nor does learning," he says. "Even sexuality holds up better than the capacity to ride a bike or play a round of golf.

"In fact, most old people are nothing like decrepit. They are vigorous people who would rather be blown up by a volcano than die of old age."

Dr. Comfort was at Stanford University Medical Center recently at the invitation of Dr. Moira Fordyce and the Department of Family, Community and Preventive Medicine. Under Fordyce's direction, a geriatric curriculum for the Medical School is being developed.

Comfort's topic was "Real and Imaginery Aging", a subject he has spent the better part of his 60 years studying in man and in animals. Educated at Trinity College, Cambridge and The London Hospital, Comfort was the first recipient of the London Doctor of Science degree in gerontology and the author of the standard textbook on gerontology, "Aging, The Biology of Senescence."

In 1974, he moved from England to California, where he has been a Fellow of the Institute of Higher Studies in Santa Barbara. He holds clinical appointments at both Stanford and U.C.L.A. and teaches Grand Rounds at Brentwood Veterans Administration Hospital in Los Angeles.

Comfort returned to teaching geriatric medicine full time because of its virtual absence in American medical schools and his belief that the provision of proper geriatric services is something that can and should be done right now.

Doctors may someday tinker with the lifespan of man, he says, but ultimately even if we live "as long as Moses", we're all going to get old.

Although the U.S. is apparently ahead of Comfort's native England in gerontology, or the study of the biology of aging, the English are more advanced in geriatric medicine—the delivery of health care services to those now old.

"You wouldn't find an old lady in a wheel chair with her bladder up to her chin and no one there to help her," says Comfort. "The main problem in the U.S. is definitely a lack of integrated services."

-more-

One of the aims of geriatric medicine, he notes, is to tailor-make programs to fit local needs.

Obviously in Canada where the winters are prohibitive, institutional care of the elderly makes more sense than home care, he says.

But in Florida, the climate might dictate a different choice.

"Geriatric services should be geared to the residents in the area," he says, "and they should be a part of the planning. Old people are the most aware of where existing services aren't working."

Comfort's interest in the elderly goes back to a scene in a London hospital during World War II.

"I saw an old man dying on one of the acute care wards," he recalls. "There were ants walking in and out of his nose and I thought to myself, we ought to be able to handle old people better than this.

"It was quite clear that geriatric medicine was one area we didn't know much about."

Another strong influence in his life was his father, who died in 1977 at the age of 94.

"He had exactly two weeks of old age," says Comfort. "I hope to be as active in my nineties as he was. He was simply not infirm."

Aside from attitudes, another major problem still confronting old people, says Comfort, is "gross overprescription" of drugs, particularly diuretics.

"There was this feisty old gent in his eighties," he says, "who suddenly began acting strangely. The geriatrician found no infection, no electrolyte imbalance and the man told him he was taking no medication.

"But when they held him upside down, the pills just tumbled out.

"I always tell doctors just starting their practice that they should get a huge plastic bag and tell their patients to put all medication in it."

Although Comfort believes the teaching of geriatric medicine should be done by specialists, the actual practice should come from a family practitioner.

"Just as there is a tendency to shunt old people out of the mainstream of society," he says, "there is a tendency to shunt geriatric medicine out of the mainstream of medicine into a geriatric ghetto."

As for himself, Comfort has found his life's work immensely rewarding.

"We are talking about the restoration and maintenance of the quality of life," he says.

City Desks: On Monday, September 22, the Palo Alto Veterans Administration Medical Center and Stanford University will dedicate a new Rehabilitative Engineering and Development Center whose work is described in the accompanying story. The dedication ceremony at Bldg. 51, 3801 Miranda Avenue, Palo Alto, will begin at 2:30 p.m. followed by an open house, and project demonstrations.

STANFORD—

"Robaids" may be how you spell relief to a disabled person.

The development of small and powerful microcomputers has paved the way for construction of robotic aids or robaids to help the paralyzed and those with limited muscular control regain some independence. Help is also coming for the mute, the blind and the deaf from computers that listen and speak.

Work on such devices is proceeding apace at the new $1 million Rehabilitative Engineering and Development Center at the Palo Alto Veteran's Administration Medical Center.

The center, established in 1978, will dedicate its new quarters on Monday, September 22. Various devices, such as "smart" robotic arms and "smart" wheelchairs, will be demonstrated at an open house at 2:30 p.m.

The center, a cooperative effort of the VA Medical Center and Stanford University schools of Engineering and Medicine, is expected to bring the most advanced technology to the aid of individuals with physical disabilities.

A most futuristic device under development is the "smart" robotic arm with its to be "even smarter" two-fingered hand. Using this device, quadraplegics will be able, with a spoken command or a turn of the head, to instruct the arm to fetch or move things.

Larry Leifer, an associate professor of mechanical engineering and the director of the center, and Inder Perkash, an associate professor of surgery, are modifying a robotic arm developed for industrial use by the Unimation Company. The arm, which is not attached to the person, but rather mounted on a wheelchair or an independent mobile platform, has 11 computers in it.

"We're trying to develop smart robotic arms that can be programmed by the patient to perform any manual task,"Leifer said. "This single, high technology device promises to give the severely disabled person control of all the other gadgets in our society. We want to replace devices that do only one thing with a device that can be programmed by the patient to do many."

At present, the hand can go up and down, sideways, back and forth and turn. Its movement can be directed by voice commands such as "move left," "flex elbow," and "close hand."

more-

Leifer and Perkash are trying to make the arm a little more human-like by programming it to respond verbally to the user's commands. An order may be met by among others, the obedient reply of "I understand the command and am proceeding," or the complaint "My batteries are getting low." A key concern of Leifer and Perkash is to develop a device the physically disabled will want to use, one they feel comfortable using. They will be consulting with potential users all during the arm's development.

A more versatile hand is also being developed for the arm. The hand will be able to pinpoint an object and then grasp, or avoid it without precise human control. This is an all-important consideration in diseases such as cerebral palsy in which movements may be jerky.

"It will be a case of the hand controlling the arm," Leifer said. The hand will 'sense' objects and in turn direct the arm's movement. The present two-fingered prototype contains a microcomputer controller and eleven light sensors.

With its slanting fingertips and bending joints, the hand could be used to bring food to the user's mouth, allowing the disabled a modicum of independence.

For those with speech problems as well as paralysis a head control device for piloting the robotic arm is being developed.

A clinical prototype should be ready next summer, Leifer said. A prototype for use in the home may be available as early as 1983, he added.

"Without paying us anything for our labor, right now it costs about $65,000 to make the arm and hand," Leifer said. "But by 1985, they could cost $20,000 or less. It depends upon how many are being made. If very few are made, they will be custom and therefore expensive."

"On a total 1.5 million dollar annual budget for the center, we could not produce the units commercially," Leifer said. "Our aim is to develop them and then bring them to a commercial interest's attention."

A spinoff from the smart arm research has been the development of the "smart" wheelchair. Through use of ultrasound sensors and a microcomputer, a wheelchair can follow a wall at a constant distance and can avoid running into things. It can also follow someone down a hall and stop if he stops. Another 3-wheelchair being developed for indoor use will be able to make tight turns and even rotations, Leifer said.

"Microcomputers are allowing us to achieve a great deal of fine control of motion, and are key to improving the aids for the disabled," Leifer said.

STANFORD—

A $15,000 gift from the Lions Club International Foundation to the division of urology at Stanford University School of Medicine will help support studies in early detection of prostate cancer, the third leading cancer in men, accounting for 17 percent of all male cancers.

Dr. Thomas Stamey, urology division chief and professor at Stanford, was recently presented the gift by a group of Lions Club officials.

"There are 55,000 cases of prostate cancer each year in the U.S., and about 22,000 deaths," noted Stamey. "The Lions Club gift will supplement ongoing studies aimed at developing a chemical test based on examination of the semen, which contains prostatic fluid. This would allow early detection of prostate cancer without relying on annual rectal examinations," he explained.

Currently, prostate cancer can be detected by rectal exam, but it is detected at a curable stage in only about 10 percent of cases, Stamey noted.

A better technique for early detection is sorely needed, he added, and could possibly help the estimated 4.9 percent of white males and 5.8 percent of non-white males who eventually develop cancer of the prostate.

Harry Aslan, a past president of the International Association of Lions Clubs, presented the gift to Stamey on behalf of the group.

"We strongly believe in serving the needs of people," Aslan said. "Supporting medical research provides a special opportunity to help many people."

Other Lions officials involved in the presentation included Joseph DiDuca of Los Gatos, international director of the International Association of Lions Clubs, Philip Ritzau of Milbrae, a past president of the International Association, William Tonelli of Burlingame, district governor of District 4-C4 of the Lions, and Donald Stanaway of Burlingame, a past district governor of 4-C4.

The Lions Club International Foundation is the philanthropic arm of the International Association of Lions Clubs representing 33,000 clubs worldwide, according to Aslan.

STANFORD—

Stanford Medical School's Department of Psychiatry and Behavioral Sciences formed its first division, the Division of Child Psychiatry and Child Development, on September 1.

The division has been created to better coordinate the clinical child psychiatry program developed over the past three years at Children's Hospital with the basic research program in child psychiatry, according to Dr. Thomas F. Anders, head of the new division.

"Too many child psychiatrists lack an academic base," he said. "We aim to integrate the academic and clinical aspects of child psychiatry and in doing so hope to train child psychiatrists who will serve in leadership roles in public and academic institutions."

"We've made it possible for a group with common interests to work in common surroundings," Dr. Thomas A. Gonda, chairman of the department, said. "The number of faculty members conducting research in child psychiatry and development has now reached a critical mass that warrants the division's formation."

Seven faculty members are in the division at present and within a year two more faculty positions will be created. In addition six physician specialists, a clinical psychologist and a social worker are part of the division.

In addition to Anders, the other faculty members are Drs. Roland Ciaranello, Anneliese Korner, P. Herbert Leiderman, Seymour Levine, Alvin A. Rosenfeld, and Alberta E. Siegel.

The research interests of the faculty are diverse. Anders investigates sleep problems in children. Leiderman studies cross-cultural approaches to child and family practices. Levine does basic research on animal behavior.

In the child psychiatry program, developed in affiliation with Stanford, clinicians treat the gamut of behavioral and emotional disorders, from bed wetting to schizophrenia. They also must work with normal children adjusting to chronic illness.

Familiarity with the frontiers of knowledge in central nervous development, child psychiatry and animal behavior and an appreciation of the cross-cultural approaches to child rearing will sharpen their clinical skills, Anders said.

In turn, the basic researchers will gain by exposure to the clinical problems in the field, he said. "New research problems may come to their attention."

Commenting on the growing field of child psychiatry and development, Gonda said: "It has become increasingly apparent that understanding how children develop is very important in understanding the behavior of adults."

STANFORD—

Once when Dr. Alfred P. Spivack was scuba diving in Honduras, he saw a man, planning to dive, whose physical condition was so poor that sport diving should have been labeled "hazardous to his health".

"He was extremely fat and he smoked constantly, puffing up the steps," says Spivack, a clinical professor of medicine at Stanford Medical School and an avid sport diver. "When he took off his shirt, there was a big red scar on his chest, which obviously meant he'd had open heart surgery. And here he was considering going scuba diving for the first time.

"I finally told the instructor that I didn't want to be on the same boat with the man because he was not taking responsibility for his own safety... and I didn't feel he should be allowed to dive."

The story, according to Spivack, illustrates the kind of person who gives a potentially beautiful sport a bad name. Any person interested in scuba diving, says Spivack, should have a complete physical check-up beforehand and also get proper training in a sport that is definitely not for everyone.

Spivack, his wife and two children are all certified by the National Association of Underwater Instructors. And in his opinion, this kind of instruction, which includes 30 hours of classtime and a weekend of supervised diving, is the bare minimum needed. Otherwise divers run the risk of panic because of an inability to handle unfamiliar situations, and in many cases, serious injury.

"The worst thing," he says, "are some of these quickie resort courses. People are usually there for a week, so they get a fast training course of a day or two... and then they're off!"

In the U.S. today, there are an estimated two to three million scuba divers and their numbers are growing. As the sport's popularity continues to grow, Spivack says, physicians have to become aware of the medical problems involved and who should be diving and who shouldn't.

At the moment, however, diving medicine is a very complex and little known field. One reason for this, notes Spivack, is many doctors find the field unattractive because of the medical and legal hassles involved. Not only is the accident rate potentially high in scuba diving, the liability factors are often difficult to determine.

But the knowledge of diving medicine is becoming more widespread as commercial diving, in particular, sparks more research in the field, and as physicians like Spivack attempt to bring more information to their communities about the medical aspects of man underwater.

Spivack is a member of the Undersea Medical Society, which cosponsored a recent training course in undersea medicine in the Florida Keys. The society's express purpose is to spread the knowledge of diving medicine.

One of the most common misconceptions about the sport, says Spivack, is that shallow diving is safe. Without an understanding of diving physiology, however, even this kind of diving can be dangerous.

"You can get into trouble with gas expansion in the lungs in 14 feet of water," says Spivack. "You are dealing with a non-compressible person (largely because of water content and bone) breathing the compressible medium of air or gases."

One of the most dangerous times apparently is when a diver returns to the surface.

On the descent, the gases a diver breathes become more compressed the deeper he goes because water pressure is increasing. (With every 33 feet, the diver is under another atmosphere of pressure, or 14.7 pounds per square inch.) The increased pressure causes the air molecules to occupy less space, much the way a balloon responds when it is squeezed. Under increased pressure, the gases also become more soluble, or dissolvable in the bloodstream and body tissues.

-more-

If a diver comes up at a measured rate, the molecules of oxygen, nitrogen and other gases have a chance to re-expand slowly and the excess gas leaves the body. But if a diver comes up too quickly, the gases expand too rapidly and form bubbles. This can happen even in a shallow dive.

These bubbles of gas, says Spivack, can be liberated anywhere in the bloodstream and the body tissues. The more serious types of decompression sickness, or the "bends" as it is more commonly known, can involve the brain and spinal cord, or other vital organs such as the heart and lungs and often result in death.

By obeying bottom time, however, Spivack says a diver can resurface without running this risk. Bottom time, according to no-decompression dive tables, indicates how long a diver can safely stay at a given depth, including the ascent time which should be no faster than 1 foot per second.

For example, a diver going to 60 feet may stay down for 60 minutes, but a minimum of one full minute is needed to reach the surface safely. A diver going to 150 feet, however, can stay down only 5 minutes and requires at least two and a half minutes in resurfacing time.

Most sport divers, says Spivack, should not go below 100 feet because it is too dangerous and because the best diving—with the most vivid colors—is between 30 and 60 feet.

Whenever he goes diving, Spivack always goes with a "buddy" since there is always the potential that something can go wrong. On one underwater venture, Spivack got a very painful ear block in his middle ear, which made him dizzy, and posed the possibility of its bursting.

"Because I knew what to do," he says, "I didn't panic. But every diver—no matter how good he is—needs help at one time or another."

Proper equipment is another factor in diving safety. According to Spivack, there is considerable variation in the quality of equipment and potential divers should investigate the differences thoroughly. But there are also practical considerations that come with experience.

"Beginners tend to get big masks that are flashy," he says, "but you have to remember that when you get water in the mask, you have to tilt the head up and exhale to blow the water out. Bigger masks require more blowing... so a low volume mask is preferable."

Of all the places he's explored underwater, Spivack likes the Red Sea best. Diving there, he says, was like being on an ocean safari.

"You see enormous schools of jack fish, sea turtles and sharks that are six feet and larger," he says. "The marine life is so plentiful that the sharks aren't interested in a large fish in a wet suit—at least not now.

"I am concerned, though, that as the Red Sea gets fished out, there will be more shark attacks on humans. But, in general, sharks are not as much of a problem for scuba divers as they are made out to be."

As long as divers remember they are "visitors in another world" and approach that world with caution and respect, says Spivack, the beauty and excitement of scuba diving is an unparalleled experience.

STANFORD—

DNA, the basic hereditary material of living things, is doing the twist.

"Its bending and twisting motions occur at the mind-boggling rate of roughly a billion every second," said Dr. Oleg Jardetzky who reported the finding in the current issue of *Biochemistry*.

He and a colleague, Dr. Michael E. Hogan, said their observations counter the traditional notion that DNA (deoxyribonucleic acid) is a rigid double-helical staircase.

DNA is "more like a staircase made of rope, than it is one of iron and concrete," said Jardetzky who directs Stanford University's Magnetic Resonance Laboratory.

The new finding was obtained by the use of nuclear magnetic resonance (NMR) spectroscopy, a technique employed by chemists for the past 30 years to identify compounds and study molecular structure.

The understanding of internal motions inside DNA is important, according to Jardetzky, because it explains how the molecule interacts with the proteins and enzymes which read the genetic code.

"Scientists had thought the DNA helix to be a rigid structure which could interact with proteins much like a key fits into a lock," he said.

"If in a particular region of the DNA helix the structure of protein meshed properly with the structure of DNA, that region could be recognized as having the proper genetic information."

Now, according to Jardetzky, it is clear the reading of DNA proteins is more complicated than the "lock and key" model.

"The ability of a protein to read information from DNA must be sensitive not only to the average structure of the helix but also to the rate and size of the wobbling which occurs in different regions," he explained.

The practical implications of the finding are wide ranging, he said.

Recombinant DNA or genetic engineering uses special enzymes as tools for cutting and splicing DNA. However, scientists don't really know how that cutting or splicing occurs.

"Advances made in the understanding of enzyme-DNA interactions at a basic level will provide the kind of information necessary for the rational design of gene splicing technology," he said.

In addition, they are important to understanding the effects of mutagens and cancer causing agents since mutations involve the disruption of the mechanism by which enzymes and other proteins read the genetic code.

The research, supported by the Division of Research Resources of the National Institutes of Health, the National Science Foundation, and the Damon Runyon-Walter Winchell Cancer Fund, were based on advances in NMR technology, Jardetzky said.

Rates of internal motions were calculated from the NMR data by a theory written in 1978 by Jardetzky and research associate Roy King.

Nuclear magnetic resonance goes back to 1945, when Dr. Felix Bloch of Stanford and Dr. E. M. Purcell of Harvard independently observed that atomic nuclei, the central cores of atoms, absorb certain frequencies of radiowaves when placed in a magnetic field.

NMR gives off a characteristic absorption spectrum, enabling scientists to identify chemicals by the types and numbers of atoms they contain.

It also provides information about the bonds holding atoms together, thus permitting the study of the shape and motions of even the most complex molecule over time.

Jardetzky's group is one of several in the United States studying molecular interactions through use of NMR.

STANFORD—

Getting reliable information on the effects of medical care requires more than just token support by the federal government.

This is the opinion of Dr. John Bunker, director of health services research at Stanford University School of Medicine.

In separate articles in the *New England Journal of Medicine* and on the opinion pages of the *New York Times*, Bunker has decried the low priority that health policy research has in Congress.

President Carter has recommended a $78 million budget for the National Centers for Health Statistics, Health Services Research, and Health Care Technology. The House Appropriations Committee has already slashed $4.25 million from this amount and the Senate may well vote further cuts.

"In the global sweep of the problems our society faces, this may not seem important," Bunker wrote. "But it is."

He said Americans spent $212.2 billion on health care last year—an average of $943 per person. The care the public receives for this amount ranges from life-saving measures to benefits too small or hard to measure.

"The experimental evidence on which to judge the effectiveness of most such care is, unfortunately, poor," Bunker said.

"Nevertheless, physicians must make decisions. By nature optimistic, they tend to believe in the effectiveness of the treatments they use.

"Poor data and professional enthusiasm encourage the over-utilization of diagnostic tests, drugs, operations and hospitals."

Congress apparently thinks that individual health agencies such as the National Institutes of Health, the Food and Drug Administration, the Center for Disease Control and others already do this work.

While these agencies attempt to evaluate their programs, the yardsticks by which they measure success or failure are not sufficient to formulate important policy decisions.

There is a reason in having strong, independent organizations to evaluate health services, Bunker said. That is to avoid the conflict of interest when federal agencies are responsible for evaluating their own performance.

The National Center for Health Statistics provides data on virtually every aspect of health, including birth and death, infant mortality, prevalence of disease and disability. The National Center for Health Services Research is responsible for studies in the organization, financing, and utilization of medical care. The National Center for Health Care Technology evaluates the effectiveness and economic impact of health care technologies.

Bunker said the argument that cuts are necessary because the economy is hurting on all fronts might have a little appeal if the level of funding for these centers had been reasonable in the past.

"When one considers that the essential services of the centers have been chronically undersupported, it makes no sense at all," Bunker said.

STANFORD—

Fifty million people in the U.S. complain of sleep disturbances, yet physicians cannot answer their most basic questions about how much sleep is necessary for good health.

This is just one indication of the fledgling status of the study of sleep disorders as a scientific and medical discipline, according to Dr. William Dement, professor of psychiatry and director of the Sleep Disorders Center at Stanford University School of Medicine.

And although some sleep disorders kill people, most medical schools offer no regular training in sleep disorder diagnosis and treatment, he adds.

These and a myriad other problems and misconceptions about sleep disorders and their treatment are being attacked in a major program, "Project Sleep," initiated by the U.S. Public Health Service and announced last December by Surgeon General Dr. Julius Richmond.

Dement was recently elected chairman of the project's Joint Coordinating Council, a group of professional organizations and consumer groups planning and carrying out the project's educational programs.

"Sleep disorder medicine is in the process of being born as a clinical field," says Dement. "A major task we face is establishing guidelines for diagnosis and treatment in a brand new field of medicine.

"But before we can promote guidelines for practice, we need to establish a consensus among the most experienced practitioners in the field," he adds. "This is a first order of business for the Council.

"While most medical specialties have emerged over many years, we are trying to collapse a century of clinical evolution into a period of a few months," he explains.

There is an urgency to educating physicians and patients about sleep disorders, Dement contends, so that the millions who now suffer from conditions like insomnia, sleep apnea and narcolepsy, will be able to benefit from the most current knowledge and therapeutic techniques and drugs available.

Project Sleep came about, in part, in response to concerns about widespread use of pills and tranquilizers for insomnia, Dement explains. A 1979 National Academy of Sciences study report Dement helped prepare, "Sleeping Pills, Insomnia and Medical Practice," pointed out some of the major concerns.

"While no one has ever clearly established the efficacy of sleeping medications, 25 million prescriptions for these medications are being written every year in the U.S.," he says.

-more-

And there are documented adverse effects from these drugs, including the dangers of serious or fatal overdose, and impaired alertness and coordination, he adds.

Another major goal of the Project Sleep Joint Coordinating Council, Dement explains, is to identify gaps in medical knowledge of sleep disorders and insomnia and to promote further research in these areas.

For instance, he explains that although millions of adults use sleeping pills continuously, almost no research on the medications' long-term effects has been conducted.

Among the public and private groups involved in the Joint Coordinating Council are the American Medical Association, the American Academy of Family Physicians, the Association of Sleep Disorders Centers, the American Psychiatric Association, Consumers Union, Ralph Nader's Health Research Group, and the Pharmaceutical Manufacturers Foundation.

Since the study and treatment of sleep disorders is emerging as a field of clinical medicine, guidelines and standards for practice are particularly important, Dement explains.

For instance, in 1976, the Association of Sleep Disorders Centers was formed to adopt and promote patient care standards that would "ensure highest quality evaluation and treatment" at the growing numbers of sleep disorders centers around the country. Dement is currently president of the Association, which represents 12 fully accredited centers.

Despite the rapid growth in numbers of specialized sleep disorders centers, both physicians and the public need more education about sleep and its problems and treatment, Dement emphasizes, citing a vivid example.

"People over 60 represent about 15 percent of the population in this country, yet they represent about 25-30 percent of the sleeping pill users.

"Preliminary evidence shows about half of all elderly people have breathing problems during sleep. For these people, sleeping pills would not be medications of choice, and might even be dangerous, since they are respiratory depressants and could worsen those breathing difficulties that already exist," he explains.

Through Project Sleep's Joint Coordinating Council, Dement hopes to increase public and professional awareness of problems such as these.

"Sleep disorders have never been considered mainstream medicine, and research in the field has suffered as a result," he explains. "We hope to overcome the temporal disadvantages the field has faced, and establish sleep research as a true discipline with a formal program of training in medical schools.

"In essence, the study of sleep and its disorders is an area as large as the biomedical sciences currently dealing with the waking state and the waking patient."

CITY DESKS: Macy is willing to be interviewed, if there is an interest.

STANFORD—

Gilbert Macy has been in and out of hospitals so many times in the past 14 years that he and his wife, Estelle, joke about writing their own Michelin guide on hospital care.

"We'd give them three sutures... instead of knives and forks for ratings," says Macy with a laugh.

Macy, a Commissioner of Human Rights in Rockland, N.Y. for nearly 15 years, was hospitalized again in April this year for a heart transplant operation at Stanford University Hospital in Palo Alto, California. Prior to this, the 51-year-old Macy had had such severe heart problems that by his own count, he'd been in and out of hospitals 34 times since 1966.

But his unusual ability to laugh at the whole ordeal is typical of what Dr. Norman Shumway, chairman of cardiovascular surgery, describes as the "heroics" of the heart transplant patient.

"Heart transplants are not for everyone," Shumway has stressed on many occasions. "The patient has to have some kind of unique zest for living—not so much a fear of dying, but in fact, a love for staying alive."

By the time he got to Stanford, Macy's zest for living already had been tested. He had survived six heart attacks and open heart surgery in 1972.

Like all heart transplant recipients, however, a new heart was his last hope. Near death, Macy knew, "time was of the essence."

Although most recipients must wait an average of two months for a donor, Macy was lucky. On April 23, 1980—eighteen days after his arrival at Stanford—he got a new heart.

His donor, a 20-year-old man, died in a motorcycle accident.

"I cannot speak highly enough about Stanford's operative and post-operative care," says Macy of his experience. "Everyone has been wonderful, friendly and concerned."

With the operation, Macy became one of Stanford's 193 transplant recipients and a member of what he calls the "most exclusive club in the world"—the survivors' club. At the moment, Macy is one of 75 living heart transplant patients.

Each year, at least 400 patients are referred to Stanford for transplantation, but only 60 are asked by the transplant team to come out for further evaluation. Of these, 40 are eventually selected for treatment, but one-third of this number die before treatment can take place.

Since the first transplant in 1968 by Dr. Christiaan Barnard in Capetown, South Africa, the length of survival for transplant recipients has increased dramatically from a matter of weeks, to one year for 70% of all recipients and five years for roughly half of them.

To stay alive, however, Shumway's "heroics" come into play. Transplant recipients must take a battery of drugs the rest of their lives, because the body never stops rejecting the foreign heart tissues. Ironically, the same drugs which have brought rejection under control leave patients susceptible to life-threatening diseases because they suppress the body's natural immunity.

Infections are not only common, they are now the leading cause of death among transplant recipients.

Since his operation, Macy admits to some anxiety over infection and also the possibility of a heart attack with his new heart.

"The heart becomes denervated from the brain in heart transplant patients," he says, "which means the normal impulses that go from the brain to the heart aren't there, and I could have a heart attack and not be aware of it... because there would be no pain."

-more-

Although there are other symptoms such as headaches, chills and a slight drop in body temperature, adds Macy, he feels more comfortable being near Stanford's cardiovascular team—at least for the moment. Technically, the risk of an undetected heart attack is slight, since an EKG (electrocardiogram) would pick up any changes in the new heart.

"I don't have any specific plans right now," says Macy, "but I'll probably do some consulting work. I can do that just as easily here, as in New York."

For many heart transplant patients, one of the greatest traumas is accepting the new heart as their own. But Macy apparently had little problem with this, compared to the ordeal of the post-operative period, which he will be in for another three months.

"The fact that you have a healthier heart is a given," he says. "The difficult thing for me has been building my body back up to a semblance of my old self.

"I played tennis semi-professionally years before I got sick. In fact, I was in pretty good shape until two years ago. That was when my doctors in Nyack, N.Y. told me, 'Don't ask us to give you a diagnosis, there is none!' "

Macy believes it will probably be another six months before he feels reasonably fit. By then, he hopes to lose the "four chins" the large doses of prednisone have caused.

"My toes are the only thing still proportionate to the rest of my body," he jokes.

Prednisone and Imuran are considered the two most indispensable drugs for heart transplant patients, but they are also the ones with the most severe side effects, such as bone fragility, bruising, and weight gain.

During the postoperative period, doctors try to reduce the amount of these drugs as much as possible without triggering the body's rejection of the new heart.

Of the last few years, Estelle Macy says, "We've run the gamut of every emotion from horror to joy."

But the Macys seem to have done so with the courage and humor.

My wife gave me a sign that reads, 'I'm unconditionally guaranteed to have defects', and that's true," says Macy, "but I'm also a survivor by nature."

CITY DESKS: PHOTO AVAILABLE ON REQUEST IF NOT INCLUDED WITH STORY.

STANFORD—

Job sharing may be a good way to bypass the seven year itch.

At least that's the experience of Joan Miller and Pat Gamberg, heart transplant nurses at Stanford University Medical Center, who are celebrating their seventh anniversary this year as job partners without a hint of the famous affliction.

Sharing one full-time position in the department of cardiovascular surgery, both women work three days a week, overlapping once weekly to handle a busy clinic schedule.

So serious are the two women about cooperative job sharing that when their EKG technician called in sick one Thanksgiving holiday, each came in to cover for exactly half the day.

Miller and Gamberg recounted the incident with amusement recently in the closet-sized office they share with two large desks, many volumes of statistics, and one cardiovascular surgeon. They explained that job sharing allows each partner to pursue her career while retaining enough freedom to spend time on family, home and other interests.

Job sharing, on the increase nationwide, nevertheless remains an unusual phenomenon. An article in the November 1978 *Stanford University Manager*, a publication of the personnel department, reported that only four non-academic University positions had been identified as being shared.

In a relatively new game Miller and Gamberg are old hands—they have been job sharing since 1973.

"And we plan to continue until they throw us out," laughed Miller, who originally held the position alone, full-time from 1970 until 1973.

Their enthusiasm for the unorthodox alliance is shared by others in the department—most importantly, by their boss.

"It's an outstanding arrangement," reported Dr. Edward Stinson, who is professor of cardiovascular surgery and principal investigator of the heart transplant program.

"Job sharing is still a new and growing phenomenon. People decide to share jobs for many reasons," explained Susie Ruggels of New Ways to Work, a nonprofit organization based in San Francisco that actively promotes the concept of job-sharing and other work/time options nationwide.

"One of the major reasons people try job sharing is to gain more time to engage in other interests or responsibilities such as child-rearing, caring for elderly parents, or continued education," Ruggels said.

In 1973, expecting her first child, Miller was looking for someone to cover during the three month period she expected to be absent.

-more-

Gamberg, then a nurse in the clinical research unit at Stanford Hospital, was exploring the possibility of half-time work, in order to gain time to spend with her two children at home.

Friends since 1964 when they were nurses in the same unit, Miller and Gamberg presented their job sharing proposal to Stinson, and embarked on the experimental arrangement with his cautious backing.

Now, Miller and Gamberg hold primary responsibility for maintaining complete medical information on all heart transplant patients from Stanford. Although not involved in the immediate post-operative care of patients in the Hospital, they are the primary medical contacts for heart transplant patients once they leave.

Together, they assist the physician in the transplant outpatient clinic, handle many routine and emergency phone calls from patients, and arrange for Hospital re-admissions and procedures whenever necessary.

They also lecture frequently on various aspects of the transplant program, and help in preparation of articles on the transplant program for publication in professional medical journals.

Although they share most duties, Miller and Gamberg have found that they complement each other in some areas, with one preferring a particular task over the other.

One of the most demanding aspects of the job is collection, filing and retrieval of data on all aspects of the heart transplant program, according to Gamberg.

"From the time a patient is accepted as a candidate for transplantation, all information is processed through our office," she explained. "Joan is expert at computing some of the statistics relating to transplant rejections in our patients, and this is an area that I prefer to leave to her."

"On the other hand, Pat is good at dealing with people, so she handles most of our employee relations and supervisory tasks," continued Miller.

"We have known each other for so long that each of us feels secure in knowing how the other will behave or react in any situation," Miller added. "The two greatest problems in this type of sharing would be competition and having other people try to play us against each other—we have avoided both pitfalls so far."

Does the team recommend job sharing for others?

"Yes; particularly if it's a mutual decision between two people who know and trust each other," Gamberg responded.

"But only if they're both extremely tolerant and extremely good," Miller laughed.

And a sense of humor probably helps most of all, they agreed.

STANFORD—

A new way of measuring a deformity of the chest wall that affects one out of two hundred children, is helping physicians at Stanford University School of Medicine learn more about surgical therapy to correct the condition.

The abnormality, known as "sunken" chest, is a major cosmetic problem for those afflicted, according to Dr. Stephen Shochat, chief of pediatric surgery. But the condition may also cause complications of the cardiovascular system that can become serious health concerns, he noted.

Surgery is sometimes performed to correct the cosmetic problem, Shochat noted. But the lack of a simple objective method for measuring the severity of the deformity has made it difficult to determine whether or not surgery helps significantly.

Shochat and his colleagues have adapted a technique developed by Japanese scientists, called moire phototopography, to measure precisely the body contours of children with sunken chests.

Moire patterns occur when two geometrical screens are superimposed. In moire phototopography, light is aimed through a screen to produce a design that is projected onto the body, Shochat explained.

The design is molded by the body contours of the patient, producing lines similar to the contour lines on a topographical map.

Using the lines as a guide, the depth of the deformity can be measured with high accuracy, Shochat said.

These body contour lines are recorded on film which can be analyzed simply and inexpensively, he explained. The technique is simple to perform, there is minimal inconvenience to the patient, and even infants can be studied, he added.

With the new measurement technique, children can be followed for evidence of early and progressive recurrence following surgery without the need for repeated x-rays, Shochat explained.

In addition, moire phototopography will enable physicians to correllate more objectively the severity of the deformity with the presence of serious complications, he noted.

Shochat reported on the use of moire photogopography in measuring sunken chest at a meeting of the American Academy of Pediatrics in Detroit on Tuesday, October 28. His colleagues in the study are Drs. John Csongradi, Gary Hartman and Lawrence Rinsky.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR INFORMATION CONTACT: Spyros Andreopoulos (415) 497-6911

STANFORD—

"The next decade for the Stanford University Medical Center will be one of maturation and consolidation of gains, according to Dr. Lawrence G. Crowley, vice president for medical affairs.

"And while the rapid growth of the late sixties and early seventies is not on our agenda, real forward motion is," he said.

"We cannot be complacent about our stature or rest on past laurels. We must not stagnate. The people, programs, and state of biomedical science here are much too dynamic to settle for the status quo."

Crowley, who recently assumed the top administrative post at the Center, spoke on future goals of the center and its relationships to the community at a staff meeting held earlier this week at Fairchild Auditorium.

Crowley said the Medical Center, which includes a university hospital, a medical school and clinics, has been helped by the crises of the late seventies "because they forced us to re-examine our values and the way this Center functions."

"In a sense, we've come of age. We've just turned 21," he said of the Medical Center which last year celebrated its twentieth year in Palo Alto.

"Like the life of an individual at one extreme and civilizations at another, an institution must not only employ its natural talents productively, but be able to adapt to changing circumstances," he said.

Crowley reported that the past 20 months were devoted to a serious re-evaluation of the Center and the relationships of its three functional units.

"This re-evaluation has been largely accomplished," he said. "The School, Hospital and the Clinics where the faculty members practice, now have identifiable and rational governance and financial systems.

"Each unit is responsible for its own program and budget within the overall umbrella of the Medical Center and the University. All these programs ended the fiscal year in a relatively strong financial position."

Crowley spoke about the physical facilities of the hospital which have been deficient in several ways—overall space, functional design, and maintenance. This has been a serious concern during the past decade and their correction is the goal of the Hospital's recently approved modernization plan.

When completed, Crowley said, "the modernization will provide almost 43 percent increase in Hospital space, including some academic space when certain Hospital functions are relocated."

He said the neonatal intensive care unit, now under construction, will be completed late winter or early spring. The modernization of the Boswell Building, which houses the University outpatient clinics, scheduled to begin in 1981, will help the faculty "provide the most modern ambulatory care in an attractive and efficient setting."

Concerning the Hospital, Crowley said these characteristics and qualities will be desirable in the 1980s.

-more-

"We have a dual role as a University hospital and regional referral center and a community hospital with special responsibilities to local citizens," he said.

"I firmly believe that only in a hospital that provides the highest quality of care will there be true quality in medical education, professional training, and clinical research.

"We must vigorously and continuously emphasize quality care for all our patients. This means more than simply the best technical care by physicians, nurses, and technologists. It means thoughtful, humanistic, indeed loving care from the moment the patient enters until the patient no longer requires hospitalization."

Crowley said that although community physicians and faculty may have different goals, their objectives are not necessarily divergent or contradictory.

"We are all united in the goal of providing the best possible care for our patients while we educate tomorrow's health professionals and improve medical procedures," he said. "The commitment is shared by all of us in a university community and underlines our responsibility to the society that has invested so much in institutions like Stanford."

Crowley said for almost two years representatives of full-time faculty and community physicians have been discussing ways of improving town-gown relationships and work more effectively toward common goals.

"Now I believe we have established the framework of a fair and practical working relationship with the community physicians," he said. "Recommendations are in the final stages of development. We will present them soon to the Hospital Board of Directors, the University and others. I anticipate we will implement these recommendations promptly in order to get on with the business at hand."

Crowley said he will make consented efforts to strengthen the Center's relationships with its major affiliated institutions—the Palo Alto Veterans Medical Center, Santa Clara Valley Medical Center, and Children's Hospital at Stanford.

"I believe the increased opportunity to offer specialized care and training at those hospitals maybe a useful way to perform our distinctive role effectively," he said.

Crowley spoke of the need for effective management.

"I predict there will be no relaxation of federal, state and community demands for levelling the steep rise in health costs," he said. "We must learn to live with these realities to provide a quality product at a reasonable cost.

"Part of the process will involve the development of approaches that will permit us to adapt to changes in the national care structure instead of reacting, as we have in the past, to these changes by crisis management."

Crowley said a university, by its very nature, is an open place.

"That openness to inquiry, to criticism, to review, to understanding of another viewpoint is a sourse of great strength. We share our results. We try to communicate freely and openly with our students, our patients, and the community."

City desks: Copies of the Report available on request if not included with story.

STANFORD—

Medical care, particularly in a teaching hospital like Stanford's, is a complicated business.

The complexity of providing care to 23,000 patients year round is the subject of Stanford University Hospital's 1979 annual report just published and available to the public from the hospital's Community Relations Office.

The report covers many key areas monitored by the Hospital's Quality Assurance Program, an effort which evolved from the need for a more systematic way of identifying and correcting problems, and to meet the requirements of the Joint Commission on Accreditation of Hospitals.

Infection control, maintaining radiological safety, and the protection of human volunteers in research projects are discussed.

"Our intent is not punitive," says Judy Bruzus, Quality Assurance Program director. "We are not so much interested in identifying the individuals responsible for problems, as in finding out where the system tends to break down, and in relaying our findings to the people who are best able to take action."

An example of how this system works was a recent Code 66 described in the report. Code 66 in hospital parlance is a red alert. A patient on the north wing's first floor nursing unit had suffered cardiac arrest.

Immediately, a team of physicians, nurses, respiratory therapists, and other support personnel rushed to the scene.

The crash cart carrying vital drugs, respiratory bags, monitors, and defibrillators was wheeled to the patient's bedside. One of the doctors took charge, while they all worked together to get the patient's heart beating again.

Meanwhile, in the background, a respiratory therapist stood with a clipboard taking notes. She noted there was some confusion at first about who would take charge.

During previous cardiopulmonary resuscitations (CPRs), she had noticed other problems, such as a crash cart's extension cord, which was too short to reach the electrical outlet, or a resuscitation bag that mulfunctioned during use. Each factor had added valuable time to the resuscitation procedures.

The therapist with the clipboard was participating in a patient care audit of CPR as performed in the Hospital. Her observations were presented to a CPR committee representing other therapists, physicians, nurses, pharmacists and Hospital engineers.

The committee recommended steps to eliminate the confusion and crowding during resuscitations, and directed the responsible departments to correct the inefficient equipment on crash carts.

A later audit showed improvements in most of these areas, according to the annual report.

Besides the departmental activities, says the report, several committees of the medical staff meet regularly to review specific aspects of medical practice, including the disciplining of physicians who fail to meet required standards.

"The business of these committees is not always as dramatic as the CPR audit, but it is nevertheless a very important means of protecting patients," the report says.

-more-

For example, "because mistakes in matching or delivering blood for transfusions can be fatal, the blood ordering or delivering system is carefully scrutinized by a blood tranfusion committee. Similarly, incomplete or unavailable medical records can delay treatment and endanger patients during emergencies.

"Thus, a medical records committee is assigned the job of ensuring that records are complete and easily retrievable."

Another busy committee is the Panel on the Use of Medical Subjects in Research. It meets each month and reviews 60 to 70 research proposals in nearly every field of medicine. The panel includes 10 physicians, a professor of ethics and philosophy, a lawyer, a registered nurse, a pharmacist, community members, and students.

"Not many are rejected outright," says panel chairman Dr. Philip Berger, professor of psychiatry and behavioral sciences, "but many go through a long process of modification to increase the benefit and decrease the risk to the patient."

This, according to the report, means that in reviewing proposals panel members must make sure that volunteers are prevented from unnecessary risks and that the researcher has obtained informed consent.

Informed consent means that the volunteers understand that they have the right to know why the experiment is being conducted, what benefits as well as risks are involved, and that they may withdraw from the study at any time without prejudicing their medical care, the report says.

Financial data and other details of the Hospital's operation are also provided in the report. For a copy, call 497-7167.

STANFORD—

Dwain N. Fullerton, associate vice president for medical development at Stanford University Medical Center, has resigned to accept a position as vice president for institute relations at the California Institute of Technology.

His appointment effective November 1 was announced Monday, October 20, by the Pasadena-based institute.

In his resignation letter to Dr. Lawrence G. Crowley, vice president for medical affairs, Fullerton wrote:

"It is with mixed emotions that I must inform you of my acceptance of the position. . . I am sorry to be leaving the School at a time when, under your leadership, the future looks so bright."

Crowley said, "Dwain has put in many years of devoted and effective service to the University and more recently to the School. We are sorry to see him go. We congratulate him and wish him well in his new position of challenge and opportunity."

A Stanford alumnus and long-time Palo Alto resident, Fullerton had headed the University's corporate relations program for 10 years before being named associate vice president at the Medical Center in 1979.

Prior to joining the University's Office of the General Secretary, he worked with the Graduate School of Business as associate director of the International Center for Advancement of Management Education, and as associate dean of a business school in Lima, Peru, modeled after the GSB.

His first fund-raising experience was in Stanford's annual fund, starting in 1960.

Fullerton earned the A.B. from Stanford in 1958 and the M.A. in 1960. In addition, he attended the National University of Chile as a Fullbright scholar.

STANFORD—

The existential approach to psychotherapy has long been viewed as a "homeless waif...not permitted into the better academic neighborhoods," says Dr. Irvin D. Yalom.

And yet most clinicians operate implicitly within this framework, he says, whether or not they are aware of it.

"In his bones," says Yalom, "the clinician appreciates a patient's (existential) concerns and responds accordingly."

These vital concerns that are shared by a patient and his therapist, according to Yalom, are not accounted for in traditional psychological theories. But they should be in the center of the therapeutic arena.

Yalom is a professor of psychiatry at Stanford University School of Medicine and the recipient of two national awards for his contributions in the fields of clinical psychiatry and research.

In his recently published book *Existential Psychotherapy* (Basic Books, New York, $18.50), Yalom says that the existential approach differs from other theories in its radically different view of the "specific forces, motives and fears that interact in the individual."

Unlike the Freudian approach, for instance, which posits that the child is governed by innate instinctual forces at conflict with a world that prevents their satisfaction, existential therapy holds that the individual is at conflict with the givens of existence, or the human condition.

Yalom identifies the four ultimate concerns of the individual as death, freedom, existential isolation and meaninglessness. Although someone else might have chosen different concepts, he says, these represent the existential experiences of Everyman, including the therapist.

"There are a number of loose approaches vaguely referred to as existential," he says. "What I've tried to do is make a synthesis of them to show there is a coherent structure to this approach."

Like all clinical approaches, however, Yalom emphasizes that the existential approach is not for all patients, or all therapists. But it is, in his opinion, a valuable, effective psychotherapeutic tool, "as rational, as coherent and as systematic as any other."

As defined in the book, death is the most obvious, most easily apprehended ultimate concern of the individual. Conflict arises between the awareness of death's inevitability and the wish to continue to be.

-more-

"The death of another," says Yalom, "is one way we are brought into confrontation with our own death. It is part of the grieving process...though often we may not realize it."

Known for his pioneering work in group counseling for dying patients, Yalom says that experience helped him treat patients, who aren't physically ill, face the concept of death.

"Properly confronted," he says, "an awareness of death has the power to enlarge us...to live fuller lives. It is an old lesson people have written about for centuries."

Yalom brings to his work a great interest in the humanities and literature, which is reflected throughout the book. He spent more than three years writing and researching it, and readily acknowledges his debt to the community of scholars at Stanford.

A graduate of Boston University Medical School, Yalom has been at Stanford since 1963.

In 1974, he received the Edward Strecker Award for psychiatric care and treatment in the U.S. and in 1979, he was awarded by the American Psychiatric Association, the Foundation's Fund Prize in Psychiatry.

Other books he has authored include *The Theory and Practice of Group Psychotherapy* (Basic Books, New York, 1975), considered a classic text in the field; *Encounter Groups: First Facts* (Basic Books, 1972); and *Every Day Gets a Little Closer* (Basic Books, 1974), an examination of the patient-psychiatrist relationship written with a former patient with the pen name of Ginny Elkins.

STANFORD—

In the bewidering maze of contradictions and myths that surround loneliness, a twin tower of truth emerges: nobody really understands its dimensions, and professionals have been frequently unsuccessful in combating it.

Now, however, two Stanford University psychiatrists have launched a study of loneliness. They are looking for volunteers to join them in their efforts to learn as much as possible about loneliness and new ways of helping them cope with it.

The psychiatrists are Dr. Irvin Yalom, a professor and author of the recent book *Existential Psychotherapy*, and Dr. Molyn Leszcz, a postdoctoral fellow in psychiatry.

"We are exploring loneliness especially in people who have been thrust abruptly into it," said Yalom. "And a couple of populations that fall in this category are persons who are bereaved, separated or divorced."

Of special interest, he added, are people who have been recently separated after a long term relationship and who have no children or other close relatives with whom they can share their concerns of feeling lonely.

In terms of format, the program will take an educational approach, Yalom explained. There will be classes, depending on the number of volunteers, which will be held weekly at Stanford.

The first class will be Wednesdays from 11:30 to 1 P.M. Classes will be limited to eight people and will be free of charge. The work is funded by a private research grant.

"Loneliness is poorly understood from the professional standpoint," Yalom said.

He and Dr. Leszcz will be looking at a couple of important dimensions.

"One dimension has to do with a person's social skills—ways of interacting with others," Yalom said.

Certain individuals, he explained, have never learned to be alone. These are people who have gone to high school and college, then into marriage without the experiences of real life.

"When they are suddenly thrust into this situation," he said, "they become distrustful of others, desperate or engage in frenetic activity to escape their loneliness."

Yalom said the second dimension under study will be whether loneliness can serve as a learning, growth-oriented activity. By maximizing a patient's physical, social and emotional strengths, one might be able to reverse the effects of loneliness.

Individuals interested in taking part in the classes should contact Ms. B. Mitchell, telephone 497-6352, for details.

STANFORD—

Numerous books have been written both on diseases and on their treatment, but nary a one—until now— has tackled prognosis.

Dr. James F. Fries of Stanford University School of Medicine and Dr. George M.Ehrlich of Hahnemann Medical College in Philadelphia, after collecting and evaluating data for three years, sending 4,000 letters and working with 400 contributors and consultants, have produced *Prognosis: Contemporary Outcomes of Disease* (Charles Press Publishers, Bowie, Md.,1981, $34.95.)

The conventional wisdom has been that prognosis is much more an art than a science, only slowly acquired by the clinician over the years; medical texts routinely ignore the subject, Fries said in a recent interview.

Without taking the art out of prognosis, his book attempts to put some hard numbers in.

"We like to think of clinical judgement as more compassionate than a calculation," he said, "but at the same time we like to base our judgements on the most precise information available. The articles in this volume attempt to strike a compromise between the extremes."

The book is a practical, working guide to 131 medical and surgical conditions. Each condition is discussed in a concise article, with graphs and recent references. When hard data are not to be had, best guesses are given.

"Prognosis, whether qualitative or quantitative, is an indispensible link between diagnosis and the treatment decision," he said. "Few patients follow the 'average' course, and the good physician must learn how to individualize the decision. Genetic, demographic, social and psychosocial variables may determine the course a disease may take and how effective a treatment will be in any one patient."

The art in medicine comes in distinguishing the individual patient from the average patient, Fries said.

"Prognosis is part and parcel of this distinction, a broadly conceived prognosis, not just one equated with life expectancy."

Fries and Ehrlich identify death, disability, discomfort, drug (therapeutic) toxicity, and dollar cost as dimensions of prognosis, ones that must be considered when tradeoffs between treatments are made.

"In addition, it's imperative to weigh these dimensions over the time course of a disease," he stressed. "A further complicating factor is that a prognosis may or may not be heavily dependent upon a specific therapy. If it is, the prognosis with and without treatment needs to be deliberated upon."

All in all, formulating an accurate prognosis is not an easy task. Fries said this is the probable reason why no one has heretofore undertaken the challenge of systematizing the prognosis of a large number of diverse diseases.

In this book, a constellation of conditions is considered: infectious, malignant, hematologic, respiratory, cardiovascular, gastrointestinal, genitourinary, gynecologic, arthritic and connective tissue, endocrine and metabolic, neurologic, and psychiatric diseases, and diseases of the skin, eyes, ears, nose and throat.

Fries, author of several other books, including the best-selling health guide "Take Care of Yourself," is an associate professor of medicine at Stanford University School of Medicine. Ehrlich is professor of medicine and director of the division of rheumatology at Hahnemann Medical College and Hospital in Philadelphia.

A symposium for persons with Parkinson's disease and their families and friends will be held at Stanford University Medical School on Sunday, October 19 at 2 P.M. in Fairchild Auditorium.

Sponsored by the United Parkinson Foundation, the meeting, one of a series throughout the country, will consist of short talks by a panel of clinical neurologists, followed by a period during which the public can ask the physicians questions.

Dr. Robert W.P. Cutler, Stanford professor of neurology, will be the chairman of the meeting. Guest speakers will be Dr. Donald B. Calne of the National Institutes of Health, Bethesda, Md.; Dr. Harold L. Klawans of Rush Medical College in Chicago; Dr. George W. Paulson of Ohio State University, Columbus; and Dr. R. Lorne Ryan of Palo Alto.

The speakers will address topics ranging from present and future treatments of the symptoms of Parkinson's disease to the many medical and social problems faced by patients and their families.

The disease, a chronic, progressive, degenerative disorder of the central nervous system, affects approximately 750,000 patients in North American, the vast majority of them over age 45.

Health care professionals are also invited to attend the symposium.

The meeting is free and no reservation is needed; also printed materials about the disease will be available at no charge.

EDITORS: ADVANCE FOR P.M. RELEASE, THURSDAY, OCTOBER 16.

STANFORD—

Heavy exposure to "laughing gas" (nitrous oxide) is no laughing matter, according to results of a recent study by researchers at Stanford University School of Medicine.

The study showed that dentists who regularly use nitrous oxide in their dental practices report certain symptoms of neurological disease at four times the rate of dentists who do not use this inhalation anesthetic.

These symptoms include numbness, tingling and/or muscle weakness.

The dentists' assistants who are also heavily exposed to nitrous oxide have a three-fold higher incidence of these non-specific neurological symptoms than their unexposed counterparts, according to the Stanford researchers.

Results of the present study were announced Thursday October 16 at the annual meeting of the American Society of Anesthesiologists in St. Louis.

The neurologic findings came from questionnaires mailed to 30,000 dentists and an equal number of dental assistants as part of a national Dental Health Survey conducted by Stanford researchers with the cooperation of the American Dental Association and the National Institute of Occupational Safety and Health.

The questionnaires asked dentists and dental assistants to estimate their occupational exposure to nitrous oxide and other anesthetic gases and to complete a brief personal health history for the ten year period, 1968-1978.

According to Dr. Jay Brodsky, assistant professor of anesthesia, although a direct cause and effect relationship cannot be proven from the data in this study alone, the evidence suggests that neurological disease from exposure to nitrous oxide may represent an important occupational hazard for dental professionals.

Dental patients would not be at risk, Brodsky added, because their exposure to the gas is brief and infrequent.

-more-

"Many medical and dental professionals have mistakenly considered nitrous oxide a non-dangerous drug," Brodsky noted.

"This study draws attention to the potential hazard of prolonged exposure to laughing gas," he explained.

The tingling, numbness and muscle weakness may represent a neurological disease similar to pernicious anemia, possibly involving an interaction between the nitrous oxide and body stores of vitamin B12.

With continued heavy exposure the symptoms may progress into more severe problems such as general weakness, gait disturbances and loss of bladder and bowel control, Brodsky warned.

Among the dentists who use gaseous anesthetics, over 80 percent use nitrous oxide exclusively while 20 percent use a combination of nitrous oxide and halogenated gases such as halothane, Brodsky reported.

His colleagues in the study are Dr. Ellis Cohen, professor of anesthesia, Dr. Byron Brown, professor of family, community and preventive medicine, Dr. Charles Whitcher, professor of clinical anesthesia, and Marion Wu, research associate in family, community and preventive medicine.

Brodsky noted that other significant health problems are also associated with the use of anesthetic gases, including increased rates of liver and kidney disease, and increased numbers of miscarriages among wives of male dentists and female assistants exposed to trace concentrations of the gases. There is also a greater incidence of birth defects in children of exposed female assistants, compared to those not exposed.

These results were reported last year.

STANFORD—

An infection that has the potential of causing mental retardation, blindness and epilepsy in thousands of babies each year could be significantly reduced if pregnant women followed simple preventive measures, doctors were better informed about the infection, and screening programs were available, according to a Stanford University professor.

The disease, called toxoplasmosis, is caused by the parasite *Toxoplasma gondii*, a ubiquitous organism chronically infecting almost 50 percent of the population in the U.S., according to Dr. Jack S. Remington and his colleague Dr. Christopher B. Wilson.

Remington is professor of medicine at Stanford and director of Allergy, Immunology and Infectious Diseases at the Palo Alto Medical Research Foundation. Wilson, a former postdoctoral scholar at the Foundation, is now at the University of Washington in Seattle.

Toxoplasmosis is usually so mild that most individuals do not know they have acquired the infection and they suffer no harmful effects.

About 25 percent of women in the child-bearing age group in the U.S. harbor the organism in their bodies. In them, the infection poses no threat to the unborn child.

But when acquired during pregnancy, 45 percent of the time the parasite passes to the unborn child where it may cause significant damage to vital organ systems, the doctors note.

Although most of these infected infants appear normal at birth, many develop severe symptoms later in life, including mental retardation and blindness.

In an article in the October 15 issue of the *American Journal of Obstetrics and Gynecology*, the Stanford researchers outline basic information both doctors and pregnant women should know, and they propose establishment of regional screening programs, on a trial basis, for early detection of the infection during pregnancy.

Since 90 percent of the women who get the infection show few outward signs and feel no symptoms, the only effective diagnosis is by blood test before and during pregnancy.

Women testing positive for antibodies prior to pregnancy (those with chronic infection) need no follow up since transmission of a mother's chronic infection to her unborn child has not been demonstrated.

But Wilson and Remington suggest that for those women testing negative, follow-up testing during pregnancy would be valuable in detecting recently acquired infections.

The calculated cost of a screening program in the U.S., based on inexpensive and reliable blood tests already available, would amount to approximately $110 million per year, less than half the calculated cost of care required if the infected babies were born, the researchers claim.

-more-

The estimated 3,300 infants born infected each year in the U.S. alone bring the total financial cost to society to $221 million, according to the researchers' cost analysis.

And the emotional burden is incalculable, they add.

Simple precautions for pregnant women to follow could also go a long way towards control of the disease, the researchers stress.

"It is the responsibility of all physicians caring for pregnant women and women attempting to conceive, to inform them appropriately about specific hygienic measures for prevention of congenital toxoplasmosis," the researchers state.

The common house cat frequently spreads the infection, and pregnant women may become infected by contact with excrement from stray cats, infected house cats or by contact with other material likely to be contaminated by cat feces. Eating raw or undercooked meat is another way the infection is easily spread.

The toxoplasma organism has three forms: an infectious one that triggers the acute infection, a chronic cyst form living dormant in animal tissues (including most meats), and an oocyst form found only in cats and shed in cat feces.

Infected house cats may shed millions of oocysts every day for as long as two weeks. The oocysts are spread by flies and cockroaches and thrive in moist soil for months.

Simple precautions include avoiding raw and rare meat by smoke-curing or cooking above 66° C., washing hands after handling raw meat and vegetables, avoiding contact with stray cats, letting someone else change the cat litter, and avoiding work in the soil or gardening without gloves.

If a pregnant woman becomes infected, she and her doctor should discuss possible actions, say the researchers, including drug therapy, therapeutic abortion, or taking the risk of infection in the fetus.

This risk is highest when the mother contracts the infection late in pregnancy. Although transmission of the infection is less likely early in pregnancy, those babies affected are more severely damaged.

The state of Oregon has mandatory screening to detect maternally acquired toxoplasmosis, testing 110,000 women per year at $1 per pregnancy, the authors report.

Wide scale screening already occurs throughout the U.S. for diseases less commonly transmitted to the fetus and newborn, such as rubella and syphilis, they observe.

And regional screening programs to detect inborn errors of metabolism have reduced the cost of diagnosis of these disorders by 90 percent or more.

"Carefully planned screening and treatment, along with prevention techniques and information, could significantly reduce the expense and the suffering currently caused by this disease," the authors conclude.

STANFORD—

Dr. Inder Perkash, associate professor of surgery at Stanford University School of Medicine, has been named to a chair in Spinal Cord Injury established for a five-year term by the Paralyzed Veterans of America (PVA).

Perkash, chief of the Spinal Cord Injury Center at the Palo Alto Veterans Medical Center, is the first faculty member of a U.S. medical school to have a chair in spinal cord injury funded by the PVA.

The chair, supported by a $260,000 grant, was announced earlier this year by Joseph Romagnano, national president of PVA, and Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean of the School of Medicine.

The chair adds to already existing programs of training and research in spinal cord injury medicine directed by Stanford faculty members and based at the Palo Alto Veterans Administration Medical Center, Crowley said.

Edward Jasper, executive director of the Bay area and Western chapter of PVA said he hopes that full endowment for the chair can be obtained in the future.

Perkash; educated in India, England and Stanford, has received recognition for his research and teaching on spinal cord injury. As a result the Palo Alto Veterans Hospital has been recently designated as a regional teaching center and singled out for expansion from its currently capacity of 30 beds to a total of 60 beds.

In his research, Perkash studied the mechanisms of bladder contraction and sphincter relaxation which are involved in spontaneous emptying of the bladder. He was responsible for one of the most important advances in their care—the emptying of the bladder without catheterization.

He also studied neurophysiological disturbances related to the bladder which cause reflex elevations of blood pressure. He developed surgical procedures which will interrupt these reflexes and relieve spinal cord patients of distressing symptoms.

Perkash, working with Stanford engineers at the VA's new Rehabilitative Engineering and Development Center opened recently, is helping in the modification and development of robotic arms and other devices to help the paralyzed and those with limited muscular control regain some independence.

The PVA was established in 1946, and was chartered by Congress in 1971. The organization has donated more than one million dollars to spinal cord injury research, and is currently supporting legislation in Congress to increase funding of the spinal cord injury program of the National Institutes of Health.

STANFORD—

A $114.8 million plan to modernize Stanford University Hospital was approved Tuesday, Oct. 14, by the general members of the Hospital Corporation.

The approval empowers the Hospital board and administration to proceed with development of architectural design to be completed by November 1981.

Hospital officials expect actual construction to begin late in 1982, but precise dates will depend on timing of approvals from local and state health planners, and city and county agencies, they said.

In pointing out the need for modernizing the Hospital, Stanford University President Donald Kennedy said, "Even the best medical science enterprises, let alone clinical research, require a first-rate environment for clinical application in order to flourish.

"A critical handicap to the improvement of this environment is the quality of Stanford's present facilities. That is why we must make a substantial investment in bringing them up to standard."

According to a planning study by Vice President for Medical Affairs Lawrence G. Crowley and Hospital Executive Director Peter Levin, one example among the numerous hospital deficiencies is the amount of support space for a hospital of this size.

"Stanford has slightly more than half the square footage of support space per bed than the national average for teaching hospitals," they wrote in a 110-page report outlining the Hospital's options. In addition, its operating rooms are inadequate.

"Patient care demand already exceeds operating room capacity, and some growth is expected over the next decade," they predicted. "The Hospital faces serious problems in this area with patient waiting lists, and surgeons having to operate during evenings and weekends."

The modernization plan will use a two-stage approach, with construction proceeding sequentially.

The first stage calls for completion of the unfinished portion of the Hospital's north wing opened in 1976, construction of a low-cost building nearby to house support activities, and remodeling of present facilities.

-more-

This stage will provide needed space for Cardiology, Radiology, Transfusion Service, Pharmacy, Facilities Department, Medical Records, Materials Storage, and Cafeteria.

The second stage calls for construction of a new four-story wing to the north of the Hospital. This would provide 12 new operating rooms, renovation of 14 existing ones, 43 intensive care beds, 44 pediatric beds, and 56 medical and surgical beds to ease overcrowding in present areas. Included in the program are plans to bring Hoover Pavilion in compliance with seismic standards.

The project will not add to the Hospital's licensed present bed capacity of 663 beds. It would provide for more efficient utilization of existing beds, Levin emphasized.

The project is expected to be financed by a combination of private borrowing, Hospital reserves, and gifts.

According to Levin, the Hospital has been authorized to seek funding through revenue bonds issued by the California Health Facilities Authority for up to $79.4 million.

The Hospital is a separate, Stanford-owned subsidiary corporation in which the University trustees are also the general members, with full authority and assets. (See related story).

STANFORD—

"Stunned is about the best word I can describe it."

These were the words of Paul Berg to the question of how he felt when he learned he had won the 1980 Nobel Prize in chemistry.

But the first word that he and two others had won the $212,000 prize did not come from the Nobel Foundation. It was from a colleague whose son had heard the news on the radio early Tuesday morning.

At first when the telephone rang Berg thought it was bad news, he told a packed press conference at Stanford University School of Medicine. "A telephone call at 5:55 a.m. normally brings bad news, not good ones," he said.

"In this particular case it was delightful news," Berg said. "Nevertheless the news was shattering to me, my wife and my son and our dog, since a number of photographers showed up shortly after and camped on our doorstep waiting for me to come out."

The 54-year old Willson Professor of Biochemistry was given one-half of the prize "for his fundamental studies of the biochemistry of nucleic acids, with particular regard to recombinant DNA," the Nobel foundation said Tuesday.

The other half of the prize, the Foundation said, will be jointly shared by Walter Gilbert, professor at Harvard University, and Frederick Sanger, director of research at MRC Laboratory of Molecular Biology at the University of Cambridge, England.

Their contributions concerned the determination of base sequences in nucleic acids, the Foundation said.

"The biochemistry of nucleic acids is about as broad a term as one can possibly imagine," Berg said. "It covers frankly most of the activities that go on in this department (biochemistry).

"Principally, the work that we have done is trying to understand how genes are organized in our chromosomes and how they function both in health and disease and normal development.,"

Berg said the breakthrough that came about five or six years ago was the ability to isolate specific genes or segments of DNA and to be able to study them in molecular detail.

"Our own work has been principally using isolated genes and learning how to reintroduce them into animal cells in order to learn something about them and their function," he said.

"The research we are doing," Berg said, "I hope will lead to a more profound and complete understanding of the molecular details of gene function."

This is very important, he explained, inasmuch as one can argue that most of human characteristics—behavior potential, longevity, susceptibility to disease—all are in large part conditioned by the genes.

"That kind of understanding will have enormous impact on our understanding and appreciation of these areas," Berg said.

-more-

In response to a question, he said that one of the practical benefits that have come out of this type of genetic research is the ability of scientists to isolate specific genes capable of directing production of very specific types of molecules that have therapeutic value.

Many of these practical advances have been highlighted in the press in recent years and include the introduction of genes into bacteria for the production of human insulin, human growth hormone, and human interferon, he said.

"I think we can expect that there will be many such enormous benefits to society," Berg said.

But Berg stressed that in his view, "The most important practical benefit will be the knowledge generated by the use of these techniques in understanding both the structure, organization and function of human and other animal genes."

He said that as knowledge about the work of normal and defective genes is gained, "We think more seriously about how to ameliorate genetically-based diseases."

He was, however, critical of scientists recently exploring such type of gene therapy. "I think attempts to apply it to humans today are premature. We don't know nearly enough to be able to do it with any assurance of success," he said.

Asked by a reporter if he had expected to win the Nobel prize, Berg quipped, "I don't think you can be a scientist and not know that there is a Nobel Prize.

"I never thought much about it," he added. "You just put the thought aside and forget it because it's not the motivation for the kind of work we do."

He said he was more concerned and interested in the recognition of people who worked with him in the past 12 years—students, postdoctoral fellows and colleagues who actually share in this award.

"It's their ideas, efforts, their devotion and commitment and the fun we had working together that made it all worthwhile," Berg said.

Berg and his wife Mildred, and 22-year-old son, John, have been invited to the Nobel Week ceremonies in Stocholm December 6 through 14.

The prize-awarding ceremony will be December 10.

News of the prize brought elated reaction from many parts of the Stanford campus.

"That's terrific. . . amazing and wonderful," said Stanford University President Donald Kennedy.

"It is a moment of great excitement and pleasure," said Vice President for Medical Affairs Lawrence G. Crowley.

Berg is now the ninth Nobel Prize winner at Stanford. The others are: Kenneth J. Arrow, economics (1972); Felix Bloch, physics (1952); Paul J. Flory, (1974); chemistry; Robert Hofstadter, physics (1961); Arthur Kornberg, physiology or medicine (1959); Linus Pauling, chemistry (1964) peace (1962); Burton Richter, physics (1976); William B. Shockley, physics (1956). Affiliated with Hoover Institution: Milton Friedman (1976) economics; Frederich Hayek (1974) economics; Alexander Sholzhenitsyn (1970) literature.

STANFORD—

Sweeping changes in the governance structure of Stanford University Hospital were adopted Tuesday, Oct. 14, by the general members of the Hospital Corporation.

"The changes define more clearly the relationship of the Hospital to the Universty," said Dr. Lawrence G. Crowley, vice president for medical affairs who under the new rules becomes also president of the Hospital.

Crowley said the Hospital, a separate, University-owned subsidiary corporation, in which the University trustees are also the general members of the Hospital Corporation, will have full authority and assets, and distinct boundaries for responsibility and accountability.

"We are taking great care, as we design the new governance structure for the Stanford Hospital," said Stanford University President Donald Kennedy last week in explaining the action to the Academic Council.

Kennedy added the goal is to maximize the Hospital's independence "because the patient care enterprise is rather special and has a political future of its own."

The Board of Hospital Directors' previous authority and responsiblity was generally limited to medical staff matters, and to advising the University president on planning, budgets, rates, and Hospital needs.

Under the amended governing bylaws, these changes will go into effect January 1981:

- The Board of Hospital Directors will have full authority and responsibility over the operations and management of the Hospital.
- The vice president for medical affairs will also hold the position of president of the Hospital, responsible to the board for overall administration.
- The Hospital board's membership will be increased from 9 to 15, and 12 of the directors will be elected by the general members of the Hospital Corporation.
- The Hospital board will include two general members, seven other citizens who are not employees of Stanford or the Hospital, of whom three must be Palo Alto residents and a practicing community physician.

-more-

® In addition, the presidents of the University and Hospital, the Hospital executive director, the University's vice president for Business and Finance, the dean of the School of Medicine, and the chairman of the Faculty Practice Plan will be elected to serve on the board. The president of the University will generally be elected as chairperson of the Hospital board.

The changes mark the first time since the inception of the Hospital that practicing physicians—both community and faculty—will serve on the board.

Stanford has a 40-year contract with the City of Palo Alto for operation of the Hospital, including priorities for bed access to community physicians and Palo Alto residents.

"None of the provisions of this contract are affected by the new bylaws," Crowley explained.

Nor are the bylaws of the medical staff affected by the changes. The medical staff is self-governing with respect to the professional work performed in the Hospital.

"The change," said Crowley, "clarifies the relationship between the Hospital and medical school which must function as separate, distinct but collaborating entities.

"The Hospital must make certain that it is and remains a University hospital offering the best possible patient care to the community, in addition to its special functions of fostering education and research."

STANFORD—

Dr. Lars Vistnes has been appointed chief of the division of plastic and reconstructive surgery at Stanford University School of Medicine.

The appointment, effective September 30, was announced by Dr. John Collins, chairman of the department of surgery.

"We look forward to a new era in the program, which is already an excellent one," Collins said.

Vistnes, associate professor of surgery, is internationally known for his work in periorbital surgery, which involves reconstruction of the area around the eye socket.

He succeeds Dr. Donald Laub, who resigned his faculty positions at Stanford Medical School January 1, 1980.

In order to devote full time to the new position, Vistnes stepped down from two posts at the Palo Alto Veterans Administration Medical Center, where he had been chief of the plastic and reconstructive surgery section since 1971, and chief of surgery since 1975.

A native of Norway, Vistnes, 53, received his undergraduate and medical education in Canada. He spent his residencies in surgery and plastic surgery in San Francisco hospitals, and was a lecturer in surgery at the University of Manitoba before coming to Stanford in 1971.

In addition to his contributions to periorbital surgery, Vistnes also initiated the use of water bed treatment for spinal cord injury patients, now a standard treatment in many hospitals. He demonstrated that the water bed provides the most effective method for relief of pressure which leads to bed sores and skin damage.

STANFORD—

Dr. Avram Goldstein, director of the Addiction Research Foundation in Palo Alto and professor of pharmacology at Stanford University, will receive the Franklin Medal for outstanding scientific achievements, the Franklin Institute announced Friday in Philadelphia.

Goldstein will be one of 11 world-renowed scientists and educators who will be honored by the Institute at its 1980 Medal Day Ceremonies October 15 in the Benjamin Franklin National Memorial.

Goldstein, who founded the nonprofit Addiction Research Foundation in 1973 to improve understanding and treatment of addictive diseases, will receive the medal for his pioneering work in small proteins called brain peptides, the Institute said.

The award citation also credits Goldstein for his research which defined the criteria for the establishment and identification of the presence of opiate receptors in the brain and his continued important contributions in the endophins.

In 1979, Goldstein discovered and isolated dynorphin, a natural brain chemical 200 times more powerful than morphine.

Such brain peptides have been shown to affect sleep, memory, blood pressure, and responses to stress and pain.

The Franklin Institute was founded in 1824 as a nonprofit organization to promote science and technology, and its awards are designed to encourage exploration in these fields.

Past receipients include Niels Bohr, Albert Einstein, Enrico Fermi, Glenn Seaborg, Marshall W. Nirenberg, and Hannes Alfven.

STANFORD—

A two-day conference on the regulation of the practice of medicine will be held October 16 through 17 at Stanford University. The conference will be in the Forum Room of the Meyer Undergraduate Library.

The second in a series of three to be held in California, the conference was initiated by the Board of Medical Quality Assurance (BMQA) in Sacramento as part of its effort to examine issues arising from consumerism and the movement of permitting paraprofessionals into the practice of medicine.

The Stanford meeting, co-sponsored by the Department of Surgery of the School of Medicine, will focus on the patient's role in health care.

Speakers at the meeting are Mark Kleiman, executive director of the Consumer Coalition for Health in Washington, D.C.; Robert M. Veatch, Ph.D., professor of medical ethics at the Kennedy Institute of Ethics, Georgetown University; and David Sobel, M.D., acting chief of Preventive Medicine at the Kaiser Permanente Medical Center in San Jose.

Kleiman's topic will be "Health Care, the Consumer's Viewpoint," at 8 P.M., October 16.

Veatch will discuss "The Emerging Role of the Patient," at 9 A.M., October 17, and Sobel will speak on "Self-Care: the Patient as a Practitioner," at 1:30 P.M.

"The ultimate goal in examining these issues is to assist the BMQA in arriving at a more comprehensive definition of what constitutes the practice of medicine in California," said Dr. Harry A. Oberhelman, a BMQA member and professor of surgery.

In recent years a growing number of paraprofessionals—nurse midwives, physician's assistants, nurse practitioners, nutritionists, optometrists, podiatrists and others have been expanding their clinical domains, and are striving for varying degrees of independence from the physician.

The guidelines of what constitutes medical practice now written into law need to be re-examined in order to aid the BMQA in its role as a regulator of health care, said Sandra Bauer, a staffer with the Sacramento-based Public Affairs Research Group which has organized the conferences.

The first conference, held in Los Angeles last month, focused on the medical profession and society.

STANFORD—

The vista from a mountain top is not the only thing that is breathtaking. Although beauty is abundant, oxygen is in short supply.

In the autumn of 1981, sixteen scientists and mountain climbers will trek up the ultimate challenge in mountaineering, Mount Everest, to study how man adapts to this oxygen shortage.

Among them will be Dr. Frank H. Sarnquist, 38, assistant professor of anesthesia at Stanford University School of Medicine and clinical chief of the department of anesthesia at the Palo Alto Veterans Administration Medical Center. He's been climbing mountains for almost 20 years.

This is the first expedition to Everest devoted primarily to medical research. Dr. John West, a physiologist at the University of California, San Diego, will lead the $500,000 expedition.

Why Mount Everest? Sarnquist explains that on Mount Everest man is near the limits of his endurance. In the ethereal heights near the summit, the barometric pressure is so low that the number of oxygen molecules in a foot of cubic air becomes periously few. In fact at the 29,028-foot summit, theoretically the air should be so rarefied that man could no longer extract enough oxygen to climb.

But he does. In 1978, although dazed and desperately short of breath, Reinhold Messner and Peter Habeler of Germany became the first humans to reach the summit without using oxygen during the ascent.

Sarnquist said the expedition will measure for the first time the barometric pressure at the summit. He suspects that it is slightly higher than the theoretical value and that's why man can make it to the top, although only barely so.

But the expedition's major interest lies in the physiological adaptions the body makes when faced with oxygen debt. The scientists will test how well their bodies and those of the mountaineers are holding up as they struggle toward the peak.

Three camps will be established: a base camp at 17,600 feet, a laboratory camp at 20,000 feet and a camp at 26,200 feet from which an assault on the summit will be made. The expedition will climb the south ridge of Everest.

At each of these camps, as well as the summit, various types of tests will be done. At the laboratory camp, the climbers will work out on a bicycle exerciser which will measure how well they're working. Chemical changes will also be measured in the blood.

Climbers going to the summit will carry small electrical instruments to monitor oxygen consumption and heart activity. "We're hoping a few of the climbers will make it," he said. They will be using oxygen intermittently.

-more-

Sarnquist is interested in one of the body's relatively long-term adaptions to oxygen shortage: the increase in the number of the red blood cells, which carry oxygen to the tissues, and their oxygen-carrying protein, hemoglobin. It may take as long as six to eight weeks after moving to a higher elevation before the body has fully compensated for the low oxygen by increasing the red blood cells.

He suspects that some people may develop too much of a good thing. Too many red blood cells cause the blood to become thick, sticky and resemble sludge. The climber becomes sluggish and slow-witted. Also the tiny blood vessels in the arms and legs and other exposed places become clogged, increasing the chance of frost bit.

This syndrome is seen in some individuals who live at high altitudes. Sarnquist has just returned from three weeks in Cerro de Pasco on the central highlands of Peru. Certain of the older people living in this Peruvian town, 14,200 feet high in the Andes, develop a "sludgy sort of blood" because they have almost twice as many red blood cells as normal.

Sarnquist, working with a group of scientists from the Center For Disease Control in Atlanta and the National Institutes of Health, removed some of the red blood cells by bleeding the patients. They put back the blood after removing the cells from it and then tested the patients on a bicycle exerciser.

Results from the Peruvian trip have not been analyzed yet, but Sarnquist said the Peruvians reported feeling better.

On the Mount Everest trip, Sarnquist will repeat this test at the 20,000 camp on any of the climbers who develop high red blood cell levels. A prefab hut heated to 72 degrees will be set up for the experiments.

He explained that there may be some down to earth benefits from this expedition. "People living and working at high altitudes and people at sea level with lung and heart problems face a similar problem: a shortage of oxygen. When people are sick you have to treat them the best way you know how. You can't do experiments using them."

"On the Everest trip, we'll be able to observe how a healthy body adjusts to an oxygen shortage. From what we learn on this trip we may better understand what is happening in the sick person at lower altitudes.

FOR IMMEDIATE RELEASE

EDITORS: Text available on request.

STANFORD—

Stanford administrators soon will seek trustee approval of a major modernization program for Stanford Hospital, President Donald Kennedy told the Academic Council Friday, Oct. 3.

During the past two years, the Medical Center has made "dramatic and encouraging progress with its most serious problems," Kennedy said.

Besides balanced budgets, the gains include appointment of Lawrence Crowley as vice-president; progress toward agreements with community physicians; and restructuring of the Hospital Board of Directors.

Kennedy put no price tag on the prospective hospital modernization program. But last April Medical Center administrators circulated a 110-page document indicating $97 million would be needed over the next six years. A team headed by Hospital Executive Director Peter Levin developed the plan, which was discussed last month by the University Board of Trustees.

The Medical Center has operated in the black financially for two years in a row and "the forecast for next year and beyond is bright," Kennedy said.

Following "determined discussions and negotiations with community physicians" over access to hospital services and clinical faculty membership, he added, "I confidently expect we will have agreement by the end of fall. . . .

"It is now quite generally understood that we need each other, respect each other, and can live together productively."

In its relations with the rest of the University, the Medical Center "is not now, has never been, and is not prospectively a financial liability to Stanford," he added. "It has brought us remarkable and diverse intellectual richness and significant prestige while bearing its own weight."

While "no one can make iron clad promises" about the future, Kennedy told the faculty, "we are taking great care, as we design the new governance structure for Stanford Hospital and as we evolve new budget and accounting procedures, to maximize independence and so minimize potential liability for the rest of the University, if only because the patient care enterprise is rather special and has a political future of its own that will be difficult to control."

A "first-rate teaching hospital, with some policy control from the teaching institution" appears to be "an essential component of medical education," he observed.

Having a "full service" Medical School and Hospital right on campus has made possible the development of a truly extraordinary enterprise in biomedical research, with important ties to other schools and departments," he said.

-more-

Among Stanford's 66 members of the National Academy of Sciences, 30 percent are in the biomedical sciences.

A few universities have tried to build biomedical research enterprises around two-year preclinical programs, but "none of these has achieved real excellence on the research side and they have had rather unhappy management histories as well," he observed.

Warnings publicized nearly two years ago that the Medical Center faced a possible cumulative shortfall of $7 million by 1982 have not materialized, Kennedy noted.

"The decline in hospital census was reversed last year, with an increase in admissions and total patient days, and also net income.

"Last year the Hospital was able to add the reserves necessary to finance its own capital improvement. A new faculty practice program was developed and agreed upon, and is providing significant new income to School programs. There is no shortfall."

Despite its relatively small size and highly publicized financial problems two years ago, Kennedy said, the Medical School is "regularly ranked among the top four or five in the U.S. It attracts superb students and possesses a unique and respected orientation toward research and academic medicine."

But he added: "Even the best basic medical science enterprises, let alone clinical research, cannot operate in a vacuum: they require a first-rate environment for clinical application in order to flourish.

"That environment is not composed only of clinical faculty. It depends strongly on Stanford's capacity to attract the best interns, residents and fellows—categories of postdoctoral trainees who do not appear on the University's degree roster, but are critically important in determining the institution's quality and reputation.

"All these relationships point to the need for a first-rate patient care capacity at Stanford. A critical handicap to the improvement of this environment is the quality of Stanford's present hospital facilities. That is why we must make an investment in bringing them up to standard."

He praised the Medical School faculty for its "significant, thoughtful effort. . .to define its ambitions for the school and to evaluate and improve its curriculum." Together with the improved performance of students on national board examinations, this "leaves one confident about the health of teaching" in the School, Kennedy said.

FOR INFORMATION CONTACT: Laura Hofstadter (415) 497-6911

STANFORD—

Nine out of ten chidren today with the malignant cancer known as Hodgkin's disease will be long-term survivors, according to a Stanford University professor.

A multidisciplinary approach involving careful "staging" (determining the extent of the disease at time of diagnosis) and modern treatment methods have contributed substantially to boosting the cure rate, said Dr. Sarah Donaldson, associate professor of radiology at Stanford University School of Medicine.

Donaldson's remarks were based on a study following 171 children with Hodgkins disease treated at Stanford University Medical Center between the years 1962 and 1980. She spoke at the third annual Bristol Myers Symposium on Cancer Research held at Stanford November 20-21.

The symposium, sponsored by the Bristol Myers company and attended by physicians and cancer researchers from around the world, dealt with advances in the understanding and treatment of malignant lymphomas, cancers of the lymphatic system.

Hodgkins disease is a type of cancer that strikes the lymphatic system, usually appearing in people between the ages of 20 and 40, Donaldson noted. About 8,000 cases overall are reported in the U.S. annually.

The disease frequently shows up as a lymph node enlargement in the neck, chest or abdomen but it can involve other tissues and organs as well.

It is one of the most curable cancers, through treatment programs involving radiation therapy and drug therapy, or chemotherapy. Much of the pioneering development of these treatment techniques was done at Stanford by Drs. Henry S. Kaplan and Saul Rosenberg, the co-chairmen of the symposium. Treatment programs may consist of radiation therapy alone, chemotherapy alone or a combination of both. Many sessions of the symposium dealt with the continuing research currently under way to determine precisely the relative risks and benefits of the various treatment modes.

-more-

"Although it was once thought that children with Hodgkin's disease fared less well than adults, the current results indicate that the course of illness and response to treatment in children does not differ from that in adults," Donaldson said.

"As cure is now a reality in patients with Hodgkin's disease, we must look to the quality of survival and carefully analyze the effects of our therapies which now yield such gratifying results," Donaldson told the audience of several hundred physicians.

Complications of treatment in children may include impairment of bone growth and development, some loss of fertility, increased susceptibility to infection, and development of a new malignant tumor.

The latter problem is the most serious, Donaldson observed. In the 171 children followed in the Stanford study, four developed second malignant tumors during treatment, she noted.

"The successful programs of yesterday and today are unfolding new questions for tomorrow. These remain questions regarding the quality of survival and the price of success. These questions are perhaps the most difficult to solve," Donaldson concluded.

Bristol Myers provides unrestricted cancer research support at five university medical centers in the U.S. and two in Europe. The grants are being applied to basic research and clinical therapy programs and constitute the largest unrestricted contribution made by a corporation in support of cancer research. The institutions involved rotate sponsoring annual symposia on aspects of cancer research.

STANFORD—

The medical conquests of today are revealing unanticipated dilemmas as survival rates increase for patients once thought incurable. These are the so-called diseases of medical progress.

A group of cancer specialists meeting at Stanford University School of Medicine November 20-21 heard how, in a small percentage of patients aided by dramatic medical therapies such as heart transplantation and cancer treatment, new malignant cancers may develop.

The symposium, sponsored by the Bristol Myers company, focused on advances in understanding and treating lymphomas, cancers of the lymphatic system.

Hodgkin's disease, one type of lymphoma, is among the most curable cancers, with a five-year survival rate of about 90 percent among patients receiving modern radiation therapy and chemotherapy treatments, explained Dr. Norman Coleman, assistant professor of radiology and medicine at Stanford.

However, in about three percent of a group of 1,096 adult Hodgkin's disease patients treated at Stanford since 1968, a new cancer of the blood (leukemia) developed after completion of treatment for Hodgkin's disease, Coleman said.

"It is extremely unlikely that the leukemia develops as part of the natural course of Hodgkin's disease unmasked by improved survival, but rather leukemia is probably induced by treatment," Coleman noted.

The incidence of leukemia differed among several groups of patients on different treatment programs, Coleman said, with no leukemia reported only in the group receiving radiation therapy alone, without chemotherapy.

In contrast, about five percent of the patients given combined radiation therapy and chemotherapy or chemotherapy alone developed leukemia, he said.

These results suggest that chemotherapy for Hodgkin's disease should be used cautiously, Coleman remarked.

However, he noted that the survival rate of patients given both chemotherapy and radiation therapy is at least as good as those receiving radiation therapy alone, despite the excess leukemia in the combined treatment group.

Therefore, the risk of adverse side effects must be carefully weighed against the potential benefits of combined therapy, Coleman noted.

-more-

Heart transplant recipients form another group of patients who develop malignant cancer at a higher than normal rate. Among 199 patients given new hearts at Stanford University since 1968, eleven have developed lymphomas, cancers of the lymphatic system, an incidence of about five percent, reported Dr. Charles Bieber, senior research associate in the Department of Cardiovascular Surgery at Stanford Medical School.

The reasons for this phenomenon are not well understood, noted Dr. Roger Warnke, assistant professor of pathology at Stanford, but it may be related, in part, to the anti-rejection medications patients must take to suppress the body's natural tendency to reject foreign heart tissue.

So far, in six of the afflicted heart transplant patients the lymphoma was discovered in time for radiation treatment to be initiated, and four patients have been treated successfully, Bieber said.

"If these lymphomas prove to be treatable, the cancers may be managed effectively," he said.

The problem of rejection of new organs in transplant patients has stimulated researchers to look for better anti-rejection techniques than those now available, Bieber explained.

Recently, researchers at Sandoz, a drug company in Switzerland, found a new drug called cyclosporin-A that has proved effective in combatting rejection in both monkeys and humans with transplants. Of 50 reported human kidney transplant patients around the world who have received the drug so far, four have developed lymphoma, Bieber said.

He noted that this is a somewhat higher incidence of lymphoma than has been observed in the heart transplant patients on conventional steroid therapy to control rejection, but much lower than the incidence of lymphoma observed in heart transplant monkeys treated with cyclosporin-A.

This possible serious side effect of cyclosporin-A will have to be monitored extremely closely when the drug begins to be used next year in transplant patients at Stanford, Bieber remarked.

The advantages of the drug will probably outweigh the risks, he predicted, but further studies are needed.

Current steroid anti-rejection therapy also has many adverse side effects, including decreased bone strength that increases susceptibility to breakage, increased susceptibility to infections, and some neurological problems.

"Development of lymphoma is a small but recognized risk for transplant patients. But as cancer research continues, this problem too will be more effectively treated," Bieber concluded.

Bristol Myers provides unrestricted cancer research support at five university medical centers in the U.S. and two in Europe. The grants are being applied to basic research and clinical therapy programs and constitute the largest unrestricted contribution made by a corporation in support of cancer research. The insitutions involved rotate sponsoring annual symposia on aspects of cancer research.

The mutual effects of exercise and oral contraceptive use on blood cholesterol levels are under investigation at the Stanford Heart Disease Prevention Program.

Researchers are seeking women volunteers between the ages of 21 and 35 in the following categories:

- using oral contraceptives and physically active;
- using oral contraceptives, with a sedentary occupation and no regular physical exercise;
- not using oral contraceptives, with a sedentary occupation and no regular physical exercise.

Volunteers will make three visits over the period of a month to the Heart Disease Prevention Program facilities at 730 Welch Road. The staff will draw small blood samples, conduct a bicycle fitness test, and determine body density by underwater weighing.

Participants will receive detailed information on their blood cholesterol levels, percentage of body fat, and their maximum oxygen transport capability (a measure of physical fitness).

Those interested in volunteering should call Jim Phelps at (415) 497-6254 for more information.

John B. Ford, 31, has been appointed director of medical development at Stanford University.

He will have overall fund raising responsibility for the Medical Center—the School of Medicine, Hospital, and Clinics, according to Lawrence G. Crowley, vice president for medical affairs, and Joel Smith, vice president for development.

Ford succeeds Dwain Fullerton who resigned recently to become vice president for institutional relations at the California Institute of Technology in Pasadena.

An associate director of development since 1977, Ford has directed the major gifts program for the Medical Center.

"John has performed outstandingly in his three years at Stanford, and before coming here, gained valuable experience at Caltech and the University of Chicago," Crowley said. "We are pleased to recognize his very considerable capabilities by this appointment."

Ford, who received his undergraduate education at Stanford, attended the University of Southern California masters program in history and public administration.

He was director of annual giving at the University of Chicago from 1975 to 1977, and prior to that had served as assistant director of special projects at Caltech.

Ford with his wife, Cynthia, and three children, lives in Los Altos.

STANFORD—

A new prescription drug called zomepirac sodium has proved more effective than intramuscular doses of morphine in treatment of pain following surgery, a Stanford University researcher reports.

Unlike morphine, which has little effect when taken orally, zomepirac sodium can be taken in pill form, explains Dr. William Forrest, associate professor of anesthesia, in the November 21 issue of the *Journal of the American Medical Association.*

The drug has received considerable attention because other studies indicate that it is not addictive and that it has impressive pain-killing potency compared to standard oral pain relief medications such as aspirin and codeine.

These results are very promising, says Forrest, because there has never before been a non-narcotic oral drug to rival intramuscular narcotic agents and surpass the oral standards like aspirin in relieving pain.

Many new drugs have side effects that limit their usefulness, Forrest notes. However, in his study involving 104 patients who had recently undergone abdominal, bone or joint surgery, side effects observed with zomepirac sodium (such as nausea, dizziness, headache, sweating and visual problems) were no greater than with morphine.

The patients studied had severe or moderate pain following surgery, and they were given a single treatment of either zomepirac in pill form or morphine in an injection, to relieve pain. In addition to measuring the extent of pain relief, the time that elapsed before the patients asked for remedication was measured.

Two different dose levels of zomepirac (100 milligrams and 200 milligrams) were administered along with two dose levels of morphine (four milligrams and eight milligrams). Five to ten milligrams of morphine is commonly prescribed for postoperative pain, Forrest explains.

"Both dose levels of zomepirac provided greater alleviation of pain than either of the morphine treatments," he observes.

In addition, at least 61 percent of the patients in each of the zomepirac treatment groups went six hours without asking for more medication. In contrast, 11 percent of the patients receiving the low dose of morphine and 16 percent receiving the higher dose completed a six hour period without asking for more medication.

Although the drug's mechanism of action is not known, Forrest says it is thought to block pain impulses mediated by chemicals called prostaglandins. This puts it in a class with many mild analgesics such as aspirin, he notes.

The drug, developed by McNeil Pharmaceutical in Pennsylvania, was recently approved by the Food and Drug Administration for relief of mild to moderately severe pain.

The company reports that more than 200 physician investigators and 4,000 patients have participated in studies of its effectiveness in treating a broad range of acute and chronic pain conditions.

STANFORD—

Sean Mooney, the Medical Center's new energy conservation manager, envisions the day when people will look at Stanford and say, "That medical center is not only one of the best in medicine, but it's also one of the best in energy conservation."

That's what he's after.

Mooney comes to Stanford with a good feel for hospitals—as opposed to industrial or purely educational settings—and for the special needs of patients, physicians and researchers. He asserts that the Medical Center's Resource Conservation Committee did much excellent groundwork from 1977 to 1979.

A certified California energy auditor with a degree in physical organic chemistry and mathematics from Pennsylvania State University, Mooney has had extensive experience as chief engineer for a Health Maintenance Organization in Oakland, and as assistant chief engineer at the University of Miami School of Medicine. Before coming to Stanford he was design engineer and campus energy manager at San Jose State University.

Continually escalating costs of energy and technology result in an increasingly large chunk of the Medical Center's budget being spent on energy, says Mooney. This means there is less left for other functions. Anticipated utilities expenditures at the Medical Center for fiscal year 1980-81 are $4.3 million.

According to Mooney, specific plans to conserve at the Medical Center include: lighting level reduction and lighting efficiency upgrades wherever possible; power factor correction to make electricity usage more efficient and save on public utilities; condensate heat recovery, to reduce steam consumption in the main complex; reconfiguration of chilled water pump controls; resetting a number of non-critical hot water temperature controls (in public restrooms, for example); modifications of a large number of fume hoods in laboratories, so they won't exhaust as much conditioned air to the outside; and a study of the new Phase One building's heating, air conditioning and ventilations systems, with possibilities for increased energy efficiency.

The program also includes analysing ways to determine areas of highest energy consumption in the Hospital, which are not always obvious.

Faced with special problems of its own, such as many shift workers during a 24-hour day, the Medical Center's strategy is, to some extent, independent from the University's. Nonetheless, in an effort to establish a unified energy policy throughout Stanford, associate director of Utilities Warren Weeks and Mooney are trying to adapt the main campus program to the Medical Center's goals.

-more-

Energy program manager on main campus, Lynda Weisberg, and assistant energy program manager Nancy Teater are in contact with Weeks and Mooney. Teater and Mooney are working closely to increase public awareness of energy conservation, which is the most critical aspect of their effort. As Mooney points out, the "nuts and bolts" don't mean anything unless people participate in implementation.

As he sees it, one of Mooney's most essential functions here is to convince employees that their ideas are important and their actions count. "People waste energy and people can save it," he says. With the disappearance of daily gas lines as reminders, Mooney sees a need for revival of the realization that energy problems aren't going away.

Campus-wide efforts, launched even before the 1973 oil embargo, have continued steadily since that two-year crisis, during which the University made appropriate sacrifices in energy usage.

Since then there have been several major technical, management and public awareness efforts, as Stanford's Energy Program Office seeks out old and new areas of waste and sets priorities for action. One example is the central steam plant, which supplies steam and chilled water to much of the campus, including the Medical Center. More than $2 million was recently spent to make it more energy-efficient.

One program now in progress on main campus involves "building energy managers," employees selected in each department to serve as overseers of energy efficiency in their respective buildings. Mooney coordinates a similar program at the Medical Center, where building energy managers are distributed according to distinct area needs, and act as important sources of information for all employees.

One additional function of the Medical Center's energy managers program will be to provide employees with information on how to conserve energy, and thus money, in their homes. Posted on bulletin boards will be tips, many from Pacific Gas and Electric itself, on cutting down home utility bills.

Mooney hopes to predict and prevent waste, rather than to try to cure it in retrospect, which is much more difficult and costly. He will work on a program of engineering and energy review, in order to determine the most economical and energy-efficient ways to run all projects.

Mooney also plans to conduct audits in the Hospital; a lighting audit will probably be the first. He intends to meter all the steam, chilled water and electricity used by the Medical Center.

By looking at how much it actually costs to operate buildings, and revealing these findings to employees, he hopes to raise the incentive to conserve.

FOR IMMEDIATE RELEASE
STANFORD --

Matti Myllyniemi, 18, the first Swedish patient to receive a heart transplant at Stanford, died at 6:45 a.m. November 12 at Stanford University Hospital.

Doctors listed the cause of death as multiple organ failure.

Myllyniemi was flown to Stanford from Sweden in critical condition on October 1. He was evaluated as a heart transplant candidate after his Swedish doctors determined that he had end-stage cardiac disease. The Swedish government paid for his transport and medical expenses at Stanford.

Myllyniemi received a new heart October 16. He remained in serious condition in an intensive care unit of Stanford Hospital until his death.

Myllyniemi's mother, who joined him at Stanford soon after his arrival in October, was at his bedside all night before he died.

His case attracted wide attention in Sweden where heart transplants are illegal because death is defined by the cessation of heartbeat rather than cessation of brain activity, as in California.

Myllyniemi was the 197th patient to receive a new heart at Stanford, which has the most active heart transplant program in the world.

(ADVANCE) FOR RELEASE SUNDAY, NOVEMBER 16, 1980

STANFORD—

Dr. Donald C. Harrison of Stanford University School of Medicine is the 1980 president-elect of the American Heart Association, it was announced Sunday, November 16, in Miami Beach, Florida, at the Association's annual meeting.

Harrison is the William G. Irwin Professor of Cardiology. He is noted for his studies with anti-arrhythmic drugs, the application of computer technology in cardiology, and development of heart-monitoring devices that may help prevent sudden death. He has published more than 450 papers in these areas.

In addition to his clinical and teaching activities at Stanford, Harrison is serving as a member of several national advisory boards and committees and as a vice president of the Interamerican Society of Cardiology.

He has also previously served as a member of the National Heart, Lung and Blood Institute's advisory committee on coronary artery disease, the Medical Research Service Merit Review Board of the Veterans Administration Hospitals, and as a trustee and vice president of the American College of Cardiology.

Harrison has provided 15 years of volunteer service in American Heart Association programs on county, state and national levels, the announcement said.

He is also a member of the Santa Clara County Heart Association board of directors.

A 1958 graduate of the Medical College of Alabama, Harrison took additional training at the Peter Bent Brigham Hospital in Boston, and did research at Harvard Medical School and at the National Heart and Lung Institute, Bethesda, Maryland. He came to Stanford in 1964, and was made chief of cardiology in 1967 at the age of 32, making him one of the youngest men ever to become head of a major cardiology unit.

Harrison lives in Los Altos, California, with his wife Laura and their three children.

STANFORD—

Operating rooms at Stanford University Hospital are too small, too few in number, and competition for their use is so fierce that many operations go late into the night or are held over until the next day or the weekend.

"You have to try and work in the operating rooms to really understand the situation," says Dr. John Collins, chief of surgery and chairman of the operating room committee that assigns block time for 10 different surgical specialties and four anesthesia groups.

"It's awful."

The problem is an extremely sensitive one, since faculty and community surgeons, as well as Hospital administrators, agree its solution hinges on completion of the $114.8 million Modernization Plan. And completion is at least six years away.

But in order to finance the plan, ultimately the Hospital will need both the community's understanding of the problem and its support.

The Hospital plan was developed by a team headed by Hospital Executive Director, Peter Levin. It states that patient care demand already exceeds operating room capacity and predicts some growth over the coming decade. And it warns:

"If Stanford takes no action in response to this problem, the quality of the Hospital as a teaching and community facility will decline, together with the ability to serve as a recognized base for educational and research programs."

Just last month, the general members of the Hospital corporation, which is composed of University trustees, acted on that warning. It approved the $114.8 million plan and empowered the Hospital board and administration to begin an architectural search. Designs and certified cost estimates, necessary for the Hospital to get a certificate of need, are expected to be completed by November, 1981.

Once the Hospital has the certificate of need in hand, says Levin, the next step is to approach the California Health Care Financing Authority and ask them to consider a request for a tax-free bond issue.

Actual construction is expected to begin in late 1982, although precise dates depend on timing of approvals from local and state health planners and city and county agencies.

Each month of delay, says Levin, costs the Hospital $1 million in cost escalation.

Under the two-stage plan, the Hospital would get 12 new operating rooms and nine to 11 existing rooms would be totally renovated, giving the Hospital a total of 21 to 23 operating rooms by 1986.

At the moment, the Hospital has only 16 operating rooms, two of which are in Hoover Pavilion and are used for minor surgical procedures. Technically, the remaining 14 operating rooms in the Main Center are all multi-purpose rooms, but at least three are unusually small and one has an immovable table with an X-ray column that limits the kind of surgery that can be done.

The resulting room crunch leaves surgeons scrambling around for operating room time, and when emergencies occur, putting elective patients on hold. It also, says Collins, exacerbates relations between faculty and community surgeons and even causes stress within the different specialities.

-more-

"When you have such an increase in demand and pressure to get into operating rooms," he says, "people resort to all sorts of maneuvers to get into them."

Inevitably, the squeeze in the operating rooms spills over into the activities of the Medical School as well.

"We end up operating much later than in most teaching hospitals," says Collins. "As a result, educational activities for house staff and Medical School students get stuffed into the weekends."

Because Stanford is an acute care institution, most of the patients who come through its doors are far sicker than those seen in other institutions. The Hospital also has an international reputation in heart transplant work and other complex and specialized surgical and medical interventions.

Both of these factors contribute to the severity of the current problem, since the average time of each operation is far greater than in most hospitals.

"This doesn't mean our surgeons are slower," says Collins. "It's just that the procedures we do here are more complicated." Often, a surgeon will underestimate his operating time, he adds, because when there aren't enough operating rooms for their patients "people are always looking for angles so that they can get whatever time might open up."

On an average day, operations are performed on 55 patients at Stanford, according to Gwen Williams, director of the operating rooms and ambulatory surgery unit.

"Most of our surgical services are overutilized right now," she says. "We don't have a lot of extra time to give them. We try to utilize the existing operating rooms as efficiently as possible by minimizing the down-time between patients (the time between operations), and offering increased staffing later in the evening.

Operating rooms at the Hospital are staffed on a 24-hour basis, with all 16 rooms available during the peak hours of 7 a.m. to 3 p.m. daily. On a yearly basis the operating room committee, which is a subcommittee of the Medical Board, assigns block time for each specialty based on use during the previous year.

When a specialty runs out of block time, or does not have priority time on a given day, says Williams, cases are put on an add list, and they are given time once priorities are out of the way.

"Emergencies take precedence over scheduled procedures," she adds.

The operating rooms at Stanford are shared by faculty surgeons, community surgeons, including the Palo Alto Clinic, the Menlo Clinic, and four surgeons from a community cardiovascular group. Roughly 60 percent of operating time goes to Stanford doctors, with the remaining 40 percent divided among the others.

But scheduling becomes even more complicated because there are four anesthesia groups, one for each surgical team.

Says Williams, "Stanford faculty anesthesiologists generally do not provide anesthesia services to community surgeons, and community anesthesiologists do not provide services to Stanford faculty.

"A lot of times this causes confusion because we can't get the proper mix of individuals."

Feeling on this issue is deeply engrained in traditional town-gown concerns.

Community surgeon, Dr. William Fielder, who is deputy chief of surgery, argues that community anesthetists were here long before the Stanford group and should be allowed to continue competing.

But he also believes the teaching commitment of the Stanford anesthetists often creates delay for other surgical groups.

Additional operating rooms, contends Fielder, will resolve this problem, along with the more pressing space concern.

Surgical delays and rescheduling operations obviously cost money. Operating rooms are important income producers for hospitals. In 1980-81, according to the Financial Department, gross revenue for operating rooms was $15.7 million or roughly 11 percent of total patient revenues at this time.

More importantly, however, more operating rooms are necessary if Stanford is to stay in the forefront of medicine. Plans to develop certain clinical services in which Stanford has been in the lead have been impossible to implement because of bed limitations and lack of operating room facilities. These include such programs as renal transplantation, orthopedic surgery, bone-marrow transplants, and microsurgery.

In the meantime, while awaiting implementation of the Modernization Plan, community surgeons at Stanford have received some relief from the Palo Alto Surgicenter—at least for minor surgery. Since it opened its doors in 1976, says Dr. Robert W. Jamplis, executive director of the Palo Alto Clinic, there have been 10,000 cases and no deaths.

"It's been an absolute boon," says Jamplis.

"By taking uncomplicated cases away from Stanford," agrees Executive Director Peter Levin, "the Surgicenter has been a big help to us."

In November, Stanford plans to open an ambulatory surgical treatment unit for minor surgery patients, which will handle ten percent of the Hospital's surgery cases. Although these cases will still be performed in the operating room suite, patients will be prepared for surgery in the new unit.

Its creation will do more to open up patient beds in the Hospital than ease the operating room crunch. Nonetheless, it is a small step towards solution of a problem generally considered the number one priority of the Hospital in the coming years.

"More operating rooms will mean less hassles for doctors and better services for patients," says Dr. Jamplis. "There is no town-gown problem with surgeons on this. It is a common concern for all of us."

STANFORD—

Infections from cytomegalovirus (CMV), a leading cause of death among premature infants treated in hospital intensive care nurseries, can be avoided by careful blood donor screening, a Stanford University School of Medicine study has found.

The three-year study was conducted to evaluate in detail the hazards of CMV infection after birth, and to determine if infection associated with transfusion could be prevented by using blood donors screened to be free of CMV.

The study found that transfusion associated CMV infections in intensive care nurseries can be reduced to zero. It also demonstrated the gravity of the problem—an overall mortality in selected subgroups of CMV-infected infants of 40 percent compared to a mortality of 6.6 percent in the same intensive care unit from other causes.

The findings are significant because CMV infections are estimated to afflict about 13,500 or 7.5 percent of the 210,000 infants born each year prematurely in the United States. This viral infection can cause pneumonia, hepatitis, hemolytic anemia and other complications. And it possibly contributes to developmental retardation and hearing loss.

The study was carried out in the departments of Pediatrics and Pathology by Anne S. Yeager, F. Carl Grumet, Elizabeth B. Hafleigh, Ann M. Arvin, John S. Bradley, and Charles Prober.

Their findings were presented Monday, November 10, at the annual meeting of the American Association of Blood Banks in Washington, D.C. A detailed report will appear later this month in the *Journal of Pediatrics*.

CMV is a common herpes-related virus transmitted from the mother to the infant during passage through the birth canal, Dr. Grumet, director of the Stanford University Blood Center, said in an interview. "But another source of infection, which is less appreciated, is blood transfusion."

In preemies transfusions are frequently required to treat shock or to replace blood lost for tests to monitor delicate bodily functions and maintain metabolic balance. But even the most minute blood samples drawn from these preemies must be replaced.

-more-

The study, utilized a sensitive antibody test developed and refined by Dr. Yeager and suited for rapid large scale donor screening, Dr. Grumet explained.

A total of 164 transfused preemies in the study received blood from 643 donors. Of the 74 infants exposed to CMV-positive blood donors, 10 or 13.5 percent were infected with CMV. Of 90 babies exposed only to CMV-negative donors, none acquired infection, according to the study.

The researchers found that prolonged hospitalization increases the risk of CMV infection since the preemies are likely to receive more blood transfusions. Conversely, CMV infections frequently result in prolonged hospitalization. Additional risk factors were the volume of blood given and the number of donors per infant.

"The cutoff point in terms of blood volume necessary to cause infection seems to be about 50 cc," Dr. Grumet said. "No infant receiving less than 50 cc of red cells became infected.

"Presumably a baby has to receive a certain dose of live virus before it gets infected," he explained.

In the study, conducted at Stanford University Hospital between 1977 and 1980, the preemies were divided into two groups. One group of infants received routine blood products from donors not tested until after transfusion. This group therefore received blood from both CMV positive and negative donors—a condition simulating normal hospital transfusion practices. The other group received blood only from donors specially pretested and shown to be CMV negative.

Because the study established, that in susceptible infants, transfusion acquired infections occurred only in recipients of positive and not in recipients of negative blood, only CMV negative blood is now used at Stanford for premature infants, Dr. Grumet said.

Donors of plasma were also screened for CMV infection, but no infections attributable to plasma transfusions were identified, the study found.

An additional benefit was also noted, the researchers reported. The use of CMV negative donors reduced exposure to the virus by staff coming into contact with infected infants.

STANFORD--

A mutant cancer cell line, developed by Stanford University scientists and used for producing human monoclonal (pure) antibodies, will be made available for research purposes to scientists around the world, the University announced Friday, November 7.

Announcements that the myeloma cell line, developed by Drs. Henry S. Kaplan and Lennart Olsson, will be made available to other scientists appeared in the journals *Nature* and *Science* this week.

"The mutant myeloma line, SKO-007, useful for making human hybridomas. . . is available to a) academic scientists under prior agreement to restrict further distribution, and b) to industry under a non-exclusive license agreement," the announcement said.

Cells for distribution to scientists will be ready to be shipped in about three weeks," said Dr. Henry S. Kaplan.

He explained that cells need to be grown to the requisite culture volume, then frozen for shipment after rigid quality control tests are completed. These steps have been under way for several weeks, he said.

Under a policy adopted by the University last week, scientists may obtain the cells by paying nominal handling costs and signing a statement that the cells will be used solely for research purposes.

"The cell line is provided as a service to the research community," said Stanford Vice President for Public Affairs Robert Rosenzweig.

Kaplan and Olsson reported the development of human monoclonal antibodies from artificially created cells, called hybridomas, in the September issue of the *Proceedings of the National Academy of Sciences.*

Until their efforts, hybridoma technology had produced only mouse antibodies which are not considered the first choice for diagnosis and treatment because of the body's natural reaction againsts foreign proteins.

Therefore, the development of pure antibodies from human cells has created great scientific interest. The pure antibodies are expected to be used as a powerful tool for studying human disease, and as a method for diagnosis of virus and bacterial infections, and detection of cancer.

STANFORD—

TO SCIENCE WRITERS AND CITY DESKS:

A two-day scientific symposium featuring some of the world's foremost experts in the field of diagnosis and treatment of malignant lymphomas will be held at Stanford University School of Medicine November 20 through 21.

The symposium, "Advances in Malignant Lymphomas," is the third in a series sponsored by Bristol-Myers Company.

The sessions will be conducted from 8 a.m. to 5:50 p.m. in the Sherman Fairchild Auditorium of the Stanford University Medical Center.

The symposium will explore the causes, immunology, pathology and treatment of malignant lymphomas.

It will be chaired by Dr. Henry S. Kaplan, D'Ambrogio Professor of Radiology and director of Stanford's Cancer Biology Research Laboratory; and Dr. Saul A. Rosenberg, professor of medicine and radiology.

Specific sessions will examine the current evidence of the role viruses may play in animal and human cancers, treatment complications, abnormalities of the immune system in cancer patients, pediatric leukemia, and research involving treatment of leukemia with artificially created mouse antibodies.

More than 400 participants, including cancer experts from the United States, Canada, Finland, France, Great Britain, Israel, Italy, and Sweden will attend.

Bristol-Myers provides unrestricted cancer research support at five university medical centers in the United States and two in Europe. The U.S. institutions include Baylor College of Medicine, the University of Chicago, the Johns Hopkins University School of Medicine, and Yale University School of Medicine.

The grants are being applied to basic research and clinical therapy programs and constitute the largest unrestricted contribution made by a corporation in support of cancer research. The institutions involved rotate sponsoring annual symposia on aspects of cancer research.

Reporters are cordially invited to attend the sessions. If you plan to come, please fill out the form below and return to the News Bureau. The program of the conference will also be sent to you, if not included with this announcement.

STANFORD—

A student entering Stanford Medical School this fall will have to spend at least $55,000 in the next four years, according to the Office of Financial Aid. And, of course, this is a conservative estimate. Inflation is still zooming. Tuition alone, fueled by inflation and increasing operating costs, rose 53% at Stanford between 1975 and 1979. The annual tuition for new students in 1980 has reached the formidable figure of $7,338, and will almost certainly keep rising.

At the other end of medical school, graduation, students are leaving with increasing debts. In the six years between the years 1973 and 1979, the average has more than doubled. In 1973, 76 students (the 85% of the class receiving financial aid from the School) had an average debt of $8,000; by 1979, the mean debt had risen to $16,800, 69% of the class needing aid. Even that figure may be deceptively low because it does not take into account accruing interest.

The problem—the ever-increasing cost of medical education—is not Stanford's alone. It's plaguing both public and private schools. Large numbers of entering medical students may accrue debts of $50,000 or more, according to a recent estimate of the Senate Committee on Labor and Human Resources.

Moreover, the escalating costs have been coupled to declining resources of student assistance, making the prognosis even poorer.

After the chorus clammering for "Meritocracy" in the 60s and 70s, the tune of the 80s may be the old refrain, "Medicine, none but the rich."

How true does the new tune ring? Apparently it has struck a responsive chord in the Congress. "Many low and middle income Americans cannot from existing sources meet the price of education in the health professions" is the opinion submitted in September by Senator Edward M. Kennedy (D-Mass.) of the Committee on Labor and Human Resources.

The private sector is also starting to harken.

In April, 1980, the Henry J. Kaiser Family Foundation of Palo Alto made an outright grant of $100,000 for medical student grants-in-aid to Stanford and to each of 12 other private medical schools. The 13 medical schools (Stanford, Case Western Reserve, University of Chicago, Duke, Harvard, John Hopkins, Columbia, University of Pennsylvania, University of Pittsburgh, University of Rochester, Washington University and Yale) formed a consortium about a decade ago to share information on common problems. The Foundaton also promised a second grant of $50,000 to those schools who could match it on a two-to-one basis, a so-called challenge grant.

Will the increasing cost of a medical school education indeed deter financially disadvantaged students, and increasingly the children of middle and even upper-middle class, from seeking admission to medical school? And if so, what impact will this have on the caliber of medical students?

-more-

Bernard W. Nelson, executive vice-president of the Kaiser Family Foundation, described the Foundation's conception of the problem this way:

"The Kaiser Family Foundation is very concerned about the cost of medical education, especially at the private institutions. Schools in the medical consortium, such as Stanford and Harvard, have traditionally played leadership roles in medical education over the years. The idea (of these grants) is to help schools increase their financial resources so that they will not be compromised.

"The challenge grant is aimed to increase grants for medical students. With the current emphasis on loans, students are now graduating with debts that are in some cases unmanageable. We want to increase the grant money available.

"Obviously, there are some students who will be able to pay, no matter what the price. But if institutions are forced to alter admission practices because of financial considerations, they will be weakened. One of the strengths of these institutions is their ability to attract first class students. We don't want financial considerations to change this."

The nation's unabating double digit inflation may make the causes of the rising costs fairly self-evident, but the reasons for the dwindling resources may not be so apparent. Therein hangs a tale.

A major role in this story is played by the Federal government, and a major theme is how the government changed its mind as to what its role should be.

The story begins in 1963. But first something must be said about the present. Medical students finance their education through grants, loans, work, and contributions from parents. Grants and loans have provided the lion's share of the costs for medical students of meager or modest means. At Stanford in the 1979-80 year, 41% of the calculated total financial need of the medical students was met through loans, 30% through grants. (Parental contributions theoretically accounted for another 7%; the rest was left up to the students.)

Understanding how the nature and amount of the federal loans and grants have changed over the years is important in understanding today's situation.

Before 1963, aid to medical students was mainly a family affair. But in response to perceived critical health manpower shortages in the nation, Congress in 1963 enacted legislation that provided direct federal support for health professions education. For nearly two decades prior to this, federal funding for health education was only a by-product of its commitment to biomedical research.

With enactment of new legislation in 1971, the attitude of Congress to the whole health manpower issue began to change. As the seventies progressed, the need to increase the aggregate supply of health professionals no longer was perceived to be the critical issue; rather it became where the physicians were settling—large cities—and what type of medicine they were practicing—lucrative specialties. Rural and inner-city areas were being neglected, as was primary care medicine.

The new perception that there really was no longer a terrible doctor shortage, coupled with the observation that doctors have an enviably high average income, resulted in a change of attitude toward student assistance programs.

Taxpayers became increasingly unwilling to subsidize medical students or schools, feeling that students should be able to borrow against their high future earnings.

The watershed year proved to be 1976. Students were told they would have to bear a greater part of the responsibility. Under the new law student assistance programs emphasized loans without interest subsidy, and the few grants left, except for those who were "exceptionally needy," required repayment in service.

The student loan program was reauthorized but on a more restricted basis. The interest rate of one newly-authorized loan program, the Health Education Assistance Loan Program (HEAL), could rise to 12%. Other government-insured, 7% interest-rate loans, available to medical students through the Higher Education Act of 1965, became less attractive to banks in days of double-digit interest rates.

Another federal health manpower bill is in the works this year. Versions passed the House and the Senate in September; attempts to reach a compromise bill will begin in November. Among the many differences between the House and the Senate versions are the student assistance provisions. While the House bill essentially continues, with modifications, the student aid programs of the 1976 law, the Senate bill proposes an almost entirely new portfolio of programs.

The Senate, realizing that it is not now just the very low income students who cannot afford a medical education, designed its bill to meet the needs of students from the entire range of economic circumstances—and to ensure that students bear total responsibility for payment of their education either through loan repayment or service payback. If the Senate version predominates, even some loans will have service paybacks.

Will debts become unmanageable? The Senate committee hypothesized this scenario in its report. If a student borrowed $8,000 a year (not an unlikely sum in the near future), the person would be $32,000 in debt at graduation. If this were a HEAL loan, at current interest rates the student would have to repay a total of $148,000 or $822 per month for 15 years, starting three years after graduation.

Because of such depressing calculations, the HEAL program has been used relatively little by medical students to date. But how long lower interest-rate loans will be available to finance the bulk of their education is not known. (Most students at Stanford now use a potpourri of loans, with varying interest rates.)

Private medical schools face a particularly acute problem because their tuition on average is three and a half times higher than that of public schools, pushing up the total cost considerably. Stanford's tuition is about average for private medical schools.

How well will the private schools compete with the public schools for the top students, if money becomes a major consideration?

"Facing an option to attend a private or a public medical school, what should be important to the student is not what it actually costs to go to medical school, but rather how much debt he will have to assume," Dr. John Steward, associate dean for student affairs at Stanford, said.

So far the debts of Stanford's grads have been comparable with many public and private medical schools. The mean indebtedness of Stanford's 1979 graduates was as low as or lower than that of the graduates of most of California's state medical schools and of the 12 other schools in the consortium, according to Dr. Laurence Kedes, director of the medical school admissions.

-more-

Stanford has accomplished this through a complex assortment of federal, state and private loans, grants, and endowments. "This is a precarious juggling act," Steward said. "We're never sure how much money will be available to us in the near future. We try to be frugal and retain some reserve for emergencies."

Up to the mid-seventies students at Stanford were told that if they matriculated, they could expect funds to be available to finish. Not so anymore.

Now, in the front of the financial aid handbook given to students is the qualifier: "We believe at this time that funds available to the School will be sufficient to meet the valid needs of our medical students during the coming year, provided that they are willing to work during the summer, to borrow, to live within what we consider to be a frugal but reasonable budget, and to obtain the calculated parental contribution.

"We cannot assure students that all of their need will be met in future years."

Stanford has yet to fail to fill any student's needs. But in 1979, half of the applicants who were accepted to the medical school but chose not to come cited financial considerations as their major reason, according to Kedes.

Stanford is looking to the private sector for help, trying to establish more predictable and steady sources of financial aid.

The alumni have helped in the past—both as individuals and through their organization. In 1975 the Medical Alumni Association activated an endowment fund established earlier for grant use and established a loan fund.

The hope at Stanford is that they will help even more in the future.

"The opportunity for talented individuals of all socio-economic and ethnic backgrounds to become physicians must be preserved," Steward said. "To do this both stable and sufficient financial aid resources are essential.

"We can no longer rely on the Federal government to bear the cost of medical education, nor should we. Those of us who have had the benefits of a medical education should assist those following in our footsteps. The Kaiser Family Foundation has given us the challenge; I hope we meet it."

STANFORD—

Because health of mind and body are often closely linked, Stanford University Medical Center is opening a new unit where patients will receive both comprehensive medical and psychiatric treatment.

Named the Comprehensive Medicine Unit, the 13-bed ward is located at the Hoover Pavilion of Stanford University Hospital, and is a joint effort of the departments of medicine and psychiatry at Stanford University School of Medicine.

According to Dr. Lorrin Koran, associate professor of clinical psychiatry and medical director of the unit, it will be one of a small number of such facilities in the country.

The unit, scheduled to open November 10, aims to help several kinds of patients—those whose medical illnesses lead to or are complicated by psychological problems, patients whose medical illnesses could be helped by behavioral techniques such as biofeedback, and psychiatric patients who are also suffering from medical disorders.

For instance, Koran explains that patients with heart disease often experience severe depression; people with chronic lung disease may be plagued by anxiety; cancer patients often experience disabling chronic pain; certain drugs administered for medical problems occasionally cause psychological symptoms; drug and alcohol abuse can bring on severe physical and mental illness; and psychiatric disorders can be complicated by medical conditions.

"It is not enough to provide either medical or psychiatric care to patients like these," he says. "But with a coordinated treatment program, we hope to improve patients' coping skills and maximize their recovery."

In addition to standard medical care, patients will receive psychiatric treatments in the new program including individual and group psychotherapy for both patients and family members, medications, and behavioral therapies such as biofeedback and relaxation training.

"For example," says Koran, "we might provide a therapy group where diabetic patients can discuss different methods of coping with the illness and related problems. We will provide them with information about their disease, review coping strategies and help each patient decide what works best. Complementary groups for the patients' family members may be helpful as well.

"We may ask patients with chronic pain to keep diaries to help them detect patterns in their behavior or activities that tend to affect the pain".

"About 20 percent of all patients on medical wards suffer from clinical depression," Koran notes. "What we learn in the new unit may help us introduce psychiatric interventions more widely to improve patient care."

In addition to psychiatrists and physicians specializing in several medical specialties, nurses who specialize in medical and psychosocial nursing, psychologists, social workers, and occupational and physical therapists all will contribute to patient care.

STANFORD—

A two-day symposium on the medical consequences of nuclear weapons and nuclear war will be held Monday and Tuesday, November 17 and 18 at the Herbst Theater, War Memorial Veterans Building at the Civic Center in San Francisco.

Sponsored by the University of California, San Francisco, Stanford University School of Medicine, and the University of California, Berkeley, School of Public Health, the symposium will include discussions of the medical effects of nuclear weapons production; psychological effects of the nuclear arms race; physical characteristics of a nuclear explosion; medical and surgical problems among survivors of a nuclear war; long term effects of nuclear explosions; and political and economic aspects of the nuclear arms race.

The symposium is organized by the the Bay Area Chapter of Physicians for Social Responsibility and the Council for a Livable World Education Fund.

A renowned faculty includes members from a broad range of medical, public health and scientific disciplines. Among the faculty members are Howard H. Hiatt, M.D., dean of the Harvard School of Public Health; Herbert Scoville, Jr., former deputy director for research of the C.I.A. and president of the Arms Control Association; Dr. Sidney Drell, professor of theoretical physics and deputy director of the Stanford Linear Accelerator Center; Stuart Finch, M.D., professor of medicine at Rutgers Medical School and former director of research, Radiation Effects Research Foundation, Hiroshima; and Gene R. LaRoque, retired Rear Admiral in the United States Navy, and director of the Center for Defense Information.

Continuing medical education credit is available for physicians who attend the symposium; a registration fee of $75 will be charged. For non-physicians who attend the symposium, there is a fee of $15, and students pay $5 to attend. Registration begins at 8 a.m. in the lobby of the Herbst Theater. The program begins at 8:50 a.m..

STANFORD—

Certified nurse-midwives will probably be delivering babies at Stanford University Hospital before the end of the year, according to Dr. William J. Aronson, chairman of the Hospital's perinatal care committee.

A proposal, drafted by Dr. W. LeRoy Heinrichs, chairman of the Department of Gynecology and Obstetrics (Gyn-Ob), to grant qualified certified nurse-midwives (C.N.M.s) staff privileges for a one-year trial period was recently approved by the Medical and the Hospital boards of Stanford.

Applications from C.N.M.s will soon be accepted and reviewed by the credentials committees of the Gyn-Ob Service and the Hospital.

The certified nurse-midwives will only handle "normal" pregnancies and deliveries, those considered low-risk. A faculty obstetrician will be called in if any problems occur during the pregnancy or the birth.

"Members of the Department have strongly supported the plan," Aronson said. This is another sign of the growing acceptance of certified nurse-midwives, a relatively recent trend.

Not until 1971, when a joint statement was issued by the American College of Obstetricians and Gynecologists, the Nurses Association of the American College of Obstetricians and Gynecologists, and the American College of Nurse-Midwives, did C.N.M.s gain the official approval of the medical profession. C.N.M.s could not legally practice in California until 1974.

Midwifery got a bad press at the turn of the century. Lay midwives were delivering babies in the home in less than sterile conditions, with resultant high rates of infant and mother death. Meanwhile, anesthesia, forceps and hygenic delivery rooms were becoming the norm for doctors, and hospitals became the safer place to have a baby. Many states outlawed midwives.

Today certified nurse-midwifery is legal in every state except Kansas, and certified nurse-midwives are trained professionals. They graduate from one of the 25 nationally-approved educational programs in midwifery (three are in California) and are solely responsible only for women having normal, low-risk pregnancies. High-risk pregnancies are attended to primarily by obstetricians, although nurse-midwives may work along with the doctor.

They are registered nurses, who have either obtained a midwifery certificate along with a master's degree, or have taken a basic midwifery course, which lasts from nine to twelve months.

By the time training is finished, a C.N.M. will have performed a minimum of 20 deliveries and newborn examinations and conducted at least 20 first visits of pregnant women.

There are now 2,100 C.N.M.s in the United States, 1,700 of whom are members of the American College of Nurse-Midwives.

Jackie Dorman, 30, and Nancy Smee, 31, are two C.N.M.s planning to apply for practice privileges at Stanford. They run the Nurse-Midwives Associates in Palo Alto, which they opened last year; they deliver between three and five babies a month.

"We offer personalized care," said Smee in a recent interview. "The initial visit is two hours long, and the succeeding visits are a minimum of a half an hour. We stay with the woman all during labor, giving her support. Within 24 hours after delivery, we make a home visit to see how everyone's doing."

-more-

"We are very accessible," said Dorman, who is pregnant and plans to have Smee deliver the baby. "We really get to know the women. We try to help them experience pregnancy and birth in a very positive way."

"These women are primed for learning—about themselves, about the body, about their partners. We don't just say, 'Do you have any questions?', we try to anticipate questions. We provide information about the common changes during pregnancy," she added.

Smee and Dorman require their patients to take childbirth classes.

If a woman develops complications during the pregnancy, Smee and Dorman refer her to an obstetrician. But they always follow the course of the pregnancy and are with the woman during labor.

"Some women prefer to go through pregnancy under the supervision of a C.N.M.," Aronson said. "Stanford is trying to be responsive to consumer requests by adding this additional dimension to the wide range of services already offered by the obstetrical unit."

Smee said that many of their patients are graduate students or nurses at Stanford.

"They are by and large well-educated and consciously seeking out alternative choices to the traditional method," she said.

Aronson said by granting certified nurse-midwives staff privileges, Stanford would be providing women who do desire an alternative choice with a safe place to have a child.

"Although certified nurse-midwives seldom deliver in the home, lay midwives usually do. Home delivery is hazardous," he said. "By allowing C.N.M.s to practice in the Hospital, we may encourage women who want a midwife to choose the safer course with a C.N.M. rather than a lay midwife."

The most recent survey of the American College of Nurse-Midwives found that 97 percent of C.N.M.s practice on hospitals or in alternative birth settings, with only 3 percent attending home deliveries.

The number of hospitals in the Bay Area where C.N.M.s can practice is limited. Only Mills Hospital in San Mateo, the Santa Clara Valley Medical Center in San Jose, San Francisco General, Mt. Zion, St. Luke's, and Moffit hospitals in San Francisco, and Merrit and Highlands hospitals in Oakland have granted C.N.M.s staff privileges.

But more and more hospitals are granting privileges, especially in rural areas like the San Joaquin Valley, according to Smee.

Aronson said that the C.N.M.s would also be a teaching asset, providing more opportunities for medical students to observe normal births.

Certified nurse-midwifery is starting to look like an idea whose time has come.

STANFORD—

A pregnancy risk prevention program is taking shape at Stanford University Medical Center, modeled after the successful Heart Disease Prevention Program.

Funded by a $30,000 planning grant from the Henry J. Kaiser Family Foundation of Menlo Park, the program will study whether through the mass media pregnant women can be taught measures that will reduce risk to their babies.

Despite advances in screening and treatment of illness in fetuses, high rates of disease and death among mothers and infants persist, especially in the lower socioeconomic areas, and among certain age and racial groups, according to the program's leader Dr. Paul Hensleigh of the department of gynecology and obstetrics.

"We can reduce the risks that result in infant deaths by educating communities about the dangers in pregnancy that can be lessened by the mother's knowledge and use of health care," he said.

The greatest cause of infant death is prematurity, he explained. It is reflected in low birth weight and associated with a number of factors, some of which can be prevented if the pregnant woman is aware of them and takes precautions.

"The mass media are potentially an effective way to make her aware," Hensleigh said.

A community-based, mass media, educational campaign has proved to be successful in the eight-year-old Stanford Heart Disease Prevention Program. In that program, communities exposed to such a campaign have been found to have reduced risks of cardiovascular disease compared with similar communities that received no media campaign.

The program will be aimed at informing the entire community, Hensleigh said. "We will want to increase the perception of pregnancy risks in the community's whole social network. This will increase the chance that pregnant women will get our message and act on it.

"During this phase of the program we're brainstorming to be sure that we've identified risk factors in pregnancy that can be changed through use of the mass media. We don't want to target factors that can't be changed or ones that even if changed won't make any difference."

A series of advisory sessions have led to the identification of the following aspects of or actions in pregnancy whose risk could be reduced by a change in the pregnant woman's attitudes or behavior, or both.

-more-

— pregnancy at a very young or old age;

— too late or too little prenatal care;

— inadequate nutrition in the preconceptional and gestational periods;

— use of cigarettes, drugs or alcohol during pregnancy; and

— unawareness of available beneficial interventions for women with a history of perinatal mortality or premature delivery.

Various groups of physicians, communication researchers, health workers, anthropologists and social scientists will during the planning phase delineate the attitudes, motivations and behaviors of pregnant women toward which the campaign should be directed. They will also decide on the media methods to be used, which could be "everything from billboards to television," according to Hensleigh.

The communities to be tested will also be chosen during the planning phase. Hensleigh says they will have about 70,000 people, and will most probably be within 100 miles of Stanford. In communities smaller than 70,000, the number of births would be too few to test whether the media campaign was working.

"The study won't be in the major metropolitan areas," he said.

The number of communities to be involved in the study has not been determined yet, but the communities tested will be matched with control communities, which are similar in their birth rates, populations and infant mortality rates, but are far enough away that the media campaign won't spill over into them.

Once the planning period is finished next April, the program will apply to a number of granting agencies to raise the estimated $3.5 million cost of the project. The project director is Dr. W. LeRoy Heinrichs, chairman of the department of gynecology and obstetrics.

STANFORD—

A search committee to seek qualified applicants for the deanship of the Stanford University School of Medicine was appointed Tuesday, November 4, by Dr. Lawrence G. Crowley, vice president for medical affairs.

The committee will be chaired by Dr. Jack Barchas, professor of psychiatry and behavioral sciences, Crowley said.

The committee will conduct a search both within and outside the Medical School and the University for qualified candidates, and will make its formal recommendations to the vice president no later than May 15.

In the search the committee is expected to consult with the faculty of the School, the administrative leadership of the School and Stanford University Hospital, the leadership of the student body and the alumni as well as appropriate individuals in other academic institutions.

"The position of dean is an extremely important leadership position for the School, Medical Center, and University," Crowley said. "The dean will be the chief academic officer of the School with responsibility for the academic programs. He will also serve as associate vice president of the Medical Center."

Until recently the posts of vice president and dean were held by the same individual. With Crowley's appointment to the post of vice president last summer, the positions were split as part of a major reorganization of the Medical Center.

The reorganization recognizes the increasing complexity and responsibilities of the two positions, and the need to be able to address the priorities of the Hospital and the School of Medicine on an even-keel basis.

Besides Barchas, members of the search committee are Frances K. Conley, assistant professor of surgery; Victor R. Fuchs, professor of economics and family, community and preventive medicine; Avram Goldstein, professor of pharmacology; I. Robert Lehman, professor of biochemistry; Hugh O. McDevitt, professor of medicine (immunology); Bruce R. Parker, associate professor of clinical radiology; Saul A. Rosenberg, professor of medicine (oncology); Irving Schulman, professor and chairman, Pediatrics; Alfred Spivack, clinical professor of medicine; James A. Spudich, professor and chairman, Structural Biology; Edward Stinson, associate professor of cardiovascular surgery; and Stephen G. Waxman, professor of neurology.

Crowley will serve as ex-officio member of the committee, and one student will be appointed shortly.

Staff support for the committee will be provided by Ms. Michael Cowan, special assistant to the vice president.

TWO STORIES

STANFORD—

Stress—how it affects your health and ways to keep it under control—will be the topic of a panel discussion at Stanford University School of Medicine at 8 p.m. Thursday November 13.

Three Stanford psychiatrists with expertise in various aspects of stress and its health effects will participate in the free program in Fairchild Auditorium, sponsored by the Friends of Psychiatry and Behavioral Sciences.

Dr. Roland Ciaranello, assistant professor of psychiatry and behavioral sciences, will discuss the biological aspects of stress, and what happens to the body when an individual is stressed. Ciaranello is also director of the laboratory of developmental neurochemistry at Stanford, and chairman of a National Academy of Sciences panel on the biologic substrates of stress.

Dr. Stewart Agras, professor of psychiatry and behavioral sciences, will discuss the uses of behavior modification treatments for stress reduction and management. Agras is also director of the laboratory for the study of behavioral medicine at Stanford.

The moderator will be Dr. Thomas Gonda, professor and chairman of the department of psychiatry and behavioral sciences.

The program is open to the public.

STANFORD—

Three Stanford University School of Medicine faculty members are among the 42 newly-elected members of the Institute of Medicine, based in Washington, D.C..

They are Jack D. Barchas, M.D., Nancy Friend Pritzker Professor of Psychiatry and Behavioral Sciences; Thomas C. Merigan, M.D., George E. and Lucy Becker Professor of Medicine, and chief of the division of infectious diseases; and Edward Rubenstein, M.D., associate dean of postgraduate medical education, and professor of clinical medicine.

Chartered in 1970 by the National Academcy of Sciences to enlist distinguished members of medical and other professions, the Institute conducts a broad range of health policy studies through the work of its committed members.

STANFORD—

Six assistant professors at Stanford are recent grantees of the Biomedical Research Support Grant awards, sponsored by the National Institutes of Health.

They are: Joseph Eliason, M.D. (surgery, ophthalmology); Vincent Hentz, M.D. (surgery, plastic and reconstructive surgery); Peter Parham, Ph.D. (structural biology); Thomas Raffin, M.D. (medicine, respiratory medicine); Branimir Ivan Sikic, M.D. (medicine, oncology and clinical pharmacology); and Robert Wall, M.D. (medicine, hematology).

A Stanford faculty committee headed by Dr. Eric Shooter, professor and chairman of the Department of Neurobiology, selects the award recipients each year.

The purpose of the grant is to assist scientists in funding basic and clinical investigations, especially in the areas of biomedical and behavioral research.

* * * * *

Eliason's research is aimed at studying the mechanism by which blood vessels grow into the cornea of the eye in response to certain diseases and injuries. A variety of diseases cause scarring and the growth of these blood vessels, which in turn result in blindness. By observing what gives rise to this growth, researchers hope to find ways of controlling it.

Hentz is developing a method to study the recovery of sensibility after nerve injury. Hoping to establish non-invasive ways to study methods of nerve repair, he anticipates that his research will lead both to better ways of assessing results of surgery and more objective measures of recovery.

Hentz is examining methods to improve hand and finger movements following tendon lacerations. He hopes to develop a new suture technique which, while allowing simpler tendon repair, will reduce the resulting scars which tend to impair function and cause stiffness.

-more-

High concentrations of oxygen can be toxic to organisms and tissue. A number of illnesses are caused by highly reactive chemicals related to oxygen, called "oxygen free radicals," which destroy tissue. Raffin is investigating the basic mechanisms of oxygen toxicity. He is also studying the ways in which different drugs may be used to reduce or prevent injury to biological systems by oxygen free radicals.

Wall is developing monoclonal antibodies to raise against isolated human blood vessel wall cells. His research is an effort to better understand the cellular basis for atherosclerosis—commonly known as hardening of the arteries, a major cause of heart attacks and strokes.

Parham is studying the structure of HLA antigens, a set of proteins on the outside of human cells which plays a role in the recognition of foreign substances and viruses infecting the cells. He and his fellow researchers hope to address the question of whether there are functional connections between HLA antigens and certain structures found inside the cell membrane. In order to ascertain this, monoclonal antibody probes will be used against both the HLA antigens and proteins of which the inner structure is composed.

Sikic is interested in why some cancer cells are resistant to certain anti-cancer drugs, and how other cancer cells may develop resistance to drug treatments. Such studies may enable physicians to predict which drugs would be useful in an individual patient, and may lead to strategies for improved chemotherapy treatments.

STANFORD—

The field of adolescent medicine is now entering its own adolescence, having been an active subdivision of pediatrics for nearly 12 years.

Since it is a relatively new field, however, little is known yet about the physical and behavioral development of normal teenagers as well as those with serious medical problems.

"In general, adolescents have been outside the mainstream of medical care," says Dr. Iris Litt, associate professor of pediatrics at Stanford University School of Medicine and director of the adolescent medicine clinic at Stanford-Children's Ambulatory Care Center.

"One reason (for this) I think is we all share in the mythology that adolescence is the healthiest time of life...There is no pressure to bring kids into the doctor after the age of 10."

Several factors, however, are beginning to change this attitude, and adolescent medicine, according to Litt, who is one of its pioneers, is finally coming into its own.

Technological advances in medical care, she says, are forcing pediatricians to look at the problems of the chronically-ill children who now survive into adolescence. But economics, adds Litt, is also playing a part, as pediatricians, faced with a falling birth rate, must look beyond traditional baby care to stay financially sound.

Litt's personal interest in adolescents goes back to the early sixties when she taught junior high briefly between college at Cornell University and her entrance into medical school at the State University of New York.

"I found I really enjoy working with adolescents," she says simply.

Throughout her professional career, Litt has written extensively on medical concerns of the adolescent, such as drug abuse, venereal disease and health care needs in general. Before coming to Stanford in 1976, she was an associate professor of pediatrics at Albert Einstein College of Medicine in the Bronx.

She also worked as an assistant director of adolescent medicine at Montefiore Hospital and Medical Center in New York and was the medical director of that institution's Juvenile Detention Center.

Most of the adolescents who come through the doors of the Stanford-Children's clinic are there for complicated diagnostic treatments, requiring an intra-disciplinary approach.

But much of the clinical research being done, including Litt's own, also involves the so-called normal teenager. In questionnaires routinely distributed to patients, says Litt, the overriding concern of this group is their physical development.

-more-

"The boys think they're too short and worry that their penises are too small," she says. "Girls are concerned that their breasts aren't large enough or that they're too tall. These are the kinds of things adolescents really worry about.

"What we try to do is address these kinds of issues...and reassure them that what they are experiencing is normal."

One-third of all pubescent males, says Litt, experience breast development, which they find frightening, but which is perfectly normal because of increased hormonal activity at this time.

"What you find," she says, "is many teenage males are experiencing this, worrying about it, but not saying anything."

Having worked with troubled and street-wise adolescents in New York, Litt found herself deeply interested in another adolescent problem—compliance, or willingness, to take prescribed medications. The issue is an important one in adolescent medicine, since the commonly held impression that this age group will be non-compliant, has often resulted in a different standard of care for them.

"Repeatedly what I saw with these teenagers," says Litt, "is that drug abusers were totally indiscriminate in what they put in their bodies.

"At the same time, I was answering consults from subspecialists about why adolescents were not taking their prescribed medications. It was an interesting paradox."

In a recent study, Litt, with Walter R. Cuskey, Ph.D., a consulting associate professor of sociology in pediatrics at Stanford's School of Medicine, looked at compliance, with special emphasis on adolescent compliance with contraceptives.

The two researchers wanted to know whether or not patient compliance with medical regimens is predictable, specifically with regard to contraceptive use.

"It is evident," says Litt, "that providing contraceptives is not enough to prevent the high rate of teenage pregnancy in this country."

Results of the study, published earlier this year in the *Journal of Pediatrics,* showed that only 45 percent of the adolescent females involved were in fact taking their prescribed birth control pills.

"Those who came to us on their own for contraceptive advice," says Litt, "did much better with compliance than those who came in with some other problem, were found to be sexually active, and then received contraceptives."

The study also showed that this group took responsibility for making its own medical appointments and for paying medical bills—suggesting, as Litt and Cuskey point out, "that encouraging autonomy in relationship to the medical visit may help to improve adolescent compliance."

At the clinic, compliance has also been studied in rheumatoid arthritis patients to determine whether adolescents take their mediation more frequently or less frequently than younger children.

"By measuring salicylate levels," says Litt, "we found that there was no difference. With each group there was non-compliance. But when the question was broken down further, we found that the earlier the teenager developed arthritis, the less compliant he or she is as an adolescent."

A similar study, which Litt is conducting with Ira Friedman, M.D., a former fellow in adolescent medicine, is currently underway, involving 50 epileptic patients from around the Bay Area. One of the questions being asked, she says, is whether a rebellious attitude towards one's parents also extends to doctors, and if so, its effects on compliance with medication.

Researchers will also be examining the role of sexual development and how it comes into play. Previous work in this area revealed that teenagers who made their own appointments had better self-images and were more comfortable with their bodies than those who allowed their parents to take the initiative in making appointments.

Still another subject of long-standing interest to Litt is the area of gynecological problems in teenage women. As in compliance, however, available data is fairly scarce, even though, as Litt notes, girls with cramps account for the highest rate of absenteeism in school on a short-term basis.

Specifically, Litt has been looking at the effects of using a mild prostaglandin inhibitor for three days in a row before menstruation as a menstrual cramp therapy. Her findings will be published shortly with Jerry Klein, another former fellow in adolescent medicine.

In the meantime, she says, research on the developmental factors in cramps is an on-going concern. Prostaglandin levels and ovulation are being studied from the first menstruation on, in conjunction with Patrick Lavin, M.D., adolescent medicine fellow.

"If we can predict who will get cramps," says Litt, "ultimately, we may be able to prevent them."

The adolescent medicine clinic is one of 27 specialty clinics at Stanford-Children's Ambulatory Care Center. The outpatient services of the two institutions were consolidated in January of this year, although inpatient care is still handled by each hospital according to need.

Dr. Litt is acting director of the center, while Dr. Ruth T. Gross, McCormick professor of pediatrics and head of ambulatory pediatrics at the Medical School, is on sabbatical leave.

STANFORD—

Kathleen Roberts has been appointed controller of Stanford University School of Medicine.

The appointment became effective December 1.

Roberts succeeds Robert Butler who is retiring from the controller position, according to David Mendelow, associate dean for administration.

As controller, Roberts is responsible for preparation of budgets and forecasts, management of Medical School funds, and for analysis of financial policies, federal regulations, market pressures and other matters that impinge on Medical School finances.

The first woman to hold the controller's position, Roberts was promoted from her previous job as financial planning analyst at the School.

A native of Canada, Roberts received a masters degree in management from Northwestern University in 1978, and has experience in financial and budget matters in both health care and academic settings.

Prior to her arrival at Stanford, Roberts worked in fiscal management and quality control for Baxter Travenol Laboratories, Inc. in Deerfield, Illinois.

She has also worked for an academic department at Northwestern University, and she carried out a variety of administrative and financial duties as an administrative resident at Northwestern Memorial Hospital in Chicago.

STANFORD—

Bedsores, a common affliction of the elderly or long-term patient, have no common treatment. Remedies range from old-fashioned sugar solutions to the use of heat lamps and Maalox.

Now, however, three nurses in the Hoover Pavilion of Stanford University Hospital have launched a one-year study of these patient pressure points, known as decubitus ulcers, in an effort to standardize care.

The three, all R.N.s, are Alba Palmieri, Linda Simpson and Gladys Kurzuk. They are trying to measure scientifically whether ulcers heal faster in a moist or dry environment. At the same time, patient comfort and nursing time involved in treatment are being evaluated.

Ultimately, the study will involve a total of 50 patients at Hoover, who will be treated with either Op-site or a combination of heat and Maalox.

Op-site, which has the texture of skin and is made from polyurethane, acts as a vaporous seal, permitting water and air to pass through, but keeping out bacteria. Thus the ulcer is protected in a moist environment.

Heat lamps and the application of Maalox, on the other hand, promote healing by keeping the ulcer dry.

"We wanted to do a comparative study rather than just look at one treatment," says Palmieri, "because we felt this would be more effective."

So far, according to Palmieri, approximately 30 patients have been treated under the study, now in its seventh month and funded under a small grant from the Acme Corporation, which makes Op-site.

Although preliminary findings do in fact favor the Op-site treatment, says Palmieri, more definitive results will not be ready until the first of the year.

One of the questions being asked, she adds, is whether or not Op-site is a cost-effective treatment.

-more-

"Obviously, if a treatment works well," says Palmieri, "it is worth the money to the patient. But this is one of the things we still have to determine."

Each patient who is treated under the study, says Palmieri, has given his or her consent. Physician consent is also obtained before proceeding with treatment.

Once treatment is begun, extensive files are kept, which contain not only personal data on such issues as patient comfort, but the length of treatment and the nursing time involved.

The files also contain both written and pictorial descriptions of each ulcer. At the moment, says Palmieri, nurses at Hoover take pictures of patient ulcers every three days until treatment is discontinued or the ulcers heal. In addition, they measure ulcer size at regular intervals with a centimeter tape.

In several cases, the nurses have been able to use both treatments on the same patient, applying Op-site to one bedsore, Maalox to another, thus eliminating variables such as patient health in assessing treatment.

(Actual application of Op-site, however, is done only by the three principal investigators, notes Palmieri, since it must be applied in a special way.)

Prior to implementing the study, decubitus ulcer patients at Stanford had been identified by several Hospital departments, including Concurrent Review and Discharge Planning, as a significant nursing concern.

Palmieri, Simpson and Kurzuk had arrived at the same conclusion on their own. And all three were interested in expanding their nursing roles into research.

At the time a proposal was drawn up, Kurzuk was working with stroke patients who were afflicted with bedsores, and Palmieri and Simpson, as clinical nurse coordinators, were considering a standardized care program for ulcer patients on their units.

Now, of course, they are hoping the results of their study will lead to a standardized care program throughout the Hospital, as well as have some national impact through publication in leading nursing journals.

As for staff reaction to the project, Palmieri says, they've been both cooperative and enthusiastic.

STANFORD—

On a moonless night an owl can swoop down unerringly upon a mouse scurrying across a dark field. The hapless mouse finds itself in the owl's talons because it has made sounds and the owl has no equal in hearing. One estimate is that an owl because of its keen hexring can catch an insect in no more light than a candle would produce at 1,170 feet.

A Stanford University Medical School researcher is investigating just how the owl pinpoints sound so precisely and thus targets its victims so accurately. Dr Eric I. Knudsen, an assistant professor in the Department of Neurobiology, explains that more is to be learned than just how owls listen. The hearing of owls and humans is alike in several important ways, he says, and by discovering how hearing in owls develops and adapts, a better understanding of human hearing may be achieved.

The decor in the complex of rooms that is Knudsen's office and lab is decidely owl. A parliament of owls under the room number welcomes one at the door. Inside, owls looking as if E.F. Hutton were speaking, peer out of the pictures on the wall, and an assistant wears an owl-embroidered lab coat. Perched on a cage in one of the rooms sits a beautiful, brown and white owl with a heart-shaped face.

"Owls hunt at night and therefore need to localize sound very accurately," says Knudsen, who studies barn owls, which belying their name can also be found living in the campus palm trees.

The broad, earnest-looking faces and the silk-soft feathers of barn owls are really adaptations to facilitate hearing, he explains. The outsize head with its broad, flat face surrounded by a ruff of feathers is a very efficient sound collector. Stiffer feathers ring the ear openings, deflecting sound into the ears.

Also, the design of the body feathers permits the owl not only to descend silently upon its prey, but also eliminates the rustling of the wings that would distract it in its tracking of the mouse.

Another less obvious adaptation, Knudsen says, is that the barn owl's right ear is cocked upward and the left ear pointed downward. This assymetry allows owls to localize sounds from above and below, he explains. A noise coming from below will be louder in the down-directed left ear, one from above will be louder in the right ear. In the up-down direction an owl's hearing is therefore superior to a human's.

But in other important respects, the two are quite similar. In distinguishing whether the sound is coming from either the left or the right, owls and humans are a good match, far better than say monkeys or cats.

Also, owls and humans hear in approximately the same frequency range. Whereas dogs and cats can hear very high pitched sounds, up to 50,000 cycles per second, humans can only hear up to 18,000 cycles per second, owls up to 12,000 cycles per second.

Another similarity is that while most mammals have movable ears (a jack rabbit is a prime example), both owls and human have fixed ears.

Knudsen wants to know how the brain's network of nerves specialized for hearing registers where a sound is coming from. One of the ways to do this is by studying the owl's behavior as it grows. Knudsen is investigating whether the owl is born with the ability to localize sound or whether it learns through trial and error.

-more-

Two things are important in pinpointing sound: the loudness or intensity of the sound, and its time or phase difference in reaching the two ears. A big bang off to the left will be heard louder and earlier in the left ear than in the right. Both ears will send messages to higher brain centers, where the messages will be compared and a decision made as to the origin of the sound.

As the bird grows, Knudsen says, the sound collector that is his face becomes larger, and progressively more efficient. The distance between the ears becomes greater, and thus it takes longer for a sound to reach the second ear. A bird can become more discriminating. Knudsen is asking whether the owl takes all of this expanding awareness into account as he is growing.

Knudsen is also investigating whether an owl can adapt when the signals reaching its brain no longer accurately reflect reality. He puts an earplug into one of the owl's ears to soften the sound in that ear. If the owl is judging by past experience, it will think the sound is farther to the opposite side than is really the case.

Knudsen reports that the owl does make the mistake and preliminary evidence suggests that eventually it will make the connection and begin to accurately pinpoint its target again.

Knudsen is also interested in how hearing and sight hook up in the brain to produce an integrated message. He is tracking the nerve cells used in hearing to various brain centers and determining how they are interacting with the nerve cells specialized for sight.

Knudsen conducts his hearing experiments in a light-tight room walled with buff-colored pads.

During the tests, infrared light is shone into the darkened room to follow the owl's actions. Neither humans nor owls can detect infrared light and so to the owl the place is pitch black. But the light can be detected with instruments.

The owl perches on a platform, a mirror strapped to its head. Knudsen beams in a sound at some measured place. He then monitors how well the owl has localized it by watching a calibrated screen for a beam of infrared light reflected by the mirror on the owl's head.

Knudsen keeps his 15 owls, with names like Leu, Too Tall, Karim, and Amanda, in an aviary so they can exercise.

For those steeped in nursery rhymes, that the owl has superb hearing may not come as a total surprise. They may remember

Here was an old owl liv'd in an oak
The more he heard, the less he spoke
The less he spoke, the more he heard
O, if men were all like that wise bird.

STANFORD—

Stanford University officials unveiled plans at a campus dinner December 9 for a $14 million cardiovascular research building that will integrate heart research activities at Stanford University.

Fundraising for the building has passed the halfway mark with $9 million already received through private gifts.

A grant of $4 million received in 1979 from the Max C. Fleischmann Foundation of Nevada enabled the University to begin planning for the building, to be located adjacent to Stanford University Hospital.

An additional $5 million in cash gifts and pledges has since been received, including a major gift from an individual after whom the building will be named when construction begins in mid-1981, according to University President Donald Kennedy.

The new heart research center represents the first major building project for the Medical Center as it starts its third decade on the Stanford campus, said Dr. Lawrence Crowley, vice president for medical affairs.

The 31,000 net square foot building will house the academic and research programs of the department of cardiovascular surgery and the division of cardiology headed by, respectively, Dr. Norman Shumway, Frances and Charles Field professor of cardiovascular surgery, and Dr. Donald Harrison, William G. Irwin professor of medicine.

"The Harrison and Shumway teams have established international reputations for excellence in teaching and research relating to cardiovascular disease," Kennedy noted. "Despite extraordinary space handicaps, they have worked successfully to revolutionize the treatment of heart disease," he added.

The Stanford groups have pioneered research and treatment in several areas of cardiovascular disease, including clinical programs in heart transplantation for end-stage heart disease patients, and treatment of cardiac arrhythmia, an abnormal heartbeat that frequently causes sudden death.

The new facility will help integrate ongoing research in these areas and will permit a more comprehensive attack on outstanding problems of cardiovascular disease, Crowley said.

-more-

"Heart disease is still the leading cause of death in the U.S. and in most developed countries," Harrison told the group of about 150 guests at the dinner. "We have made great progress against heart disease but it remains a major cause of premature death.

"We need to understand the basic physiology and basic cellular processes that lead to heart disease, and to do this requires collaboration among many scientific disciplines."

Stanford is uniquely equipped to carry out a comprehensive program of this kind, Harrison said. Collaborative research with other departments in the Medical Center, with faculty from various departments in the University, and close contacts with many of the technological industries in the area have contributed to much of the progress that has already been made against cardiovascular disease, he noted.

New laboratory space in the building will accommodate cardiovascular specialists in radiology, pediatrics, anesthesia, pharmacology, immunology and pathology, Harrison said.

In addition, faculty from University departments such as physics, biology, computer science and engineering will have space for collaborative research.

Among the major research projects currently under way in Harrison's division are studies on cardiac pharmacology, or how drugs affect the heart, particularly cardiac arrhythmias; applications of computer systems and other advanced technology to early diagnosis of heart disease and monitoring the course and extent of disease in patients; and studies on the prevention and treatment of coronary artery disease.

"It is of utmost importance that successful and precise laboratory investigations precede any clinical adaptation of new and innovative techniques of surgical treatment," Shumway said.

In addition to continuing research that has steadily improved clinical results in cardiac transplantation and has made Stanford's heart transplant program the most active and successful in the world (70 percent of the heart transplant patients now live at least one year and 50 percent live five years), Shumway's department is actively pursuing other studies in cardiac replacement, including combined heart and lung transplantation, and development of a partial mechanical replacement for a diseased heart.

The architect for the building is the firm of Hellmuth, Obata and Kassabaum, based in St. Louis, Missouri and in San Francisco.

-more-

Preliminary plans for the building, which will be directly northeast of the Hospital, include a lower level animal facility, ground floor research laboratory space, and an upper level comprising faculty and staff office areas, and library and conference space.

A new training program for postdoctoral fellows will also be located in the building, allowing cardiovascular specialists to pursue training and research opportunities in a wide variety of disciplines.

Kennedy acknowledged the University's appreciation for several major gifts from individuals and foundations which have been received to support construction of the building.

The Max C. Fleischmann Foundation of Reno has supported numerous projects at Stanford Medical Center, including several research laboratories. Until its dissolution earlier this year, the Foundation maintained an interest in a broad spectrum of fields, both medical and non-medical. Mr. Francis Breen, a trustee of the Foundation and a Stanford Law School alumnus, noted that in supporting construction of the cardiovascular building, the Foundation hopes in the future to help many patients who suffer from heart disease.

Mrs. Louis Kovitz of Los Altos, the widow of the late Dr. Kovitz, and her daughter, Susi Kovitz Kohan are among the early supporters of the building project. Prior to Dr. Kovitz' death from cardiac disease in 1979, the Kovitz' also established a Visiting Lectureship at the School of Medicine to bring distinguished physicians from around the world to Stanford. Dr. Kovitz, a native of Baltimore, received his M.D. degree from Washington University in 1929. He became a specialist in industrial medicine and surgery and was the first medical director of Lockheed Missile and Space Corporation.

Mr. and Mrs. Mervin Morris of Atherton have had a longstanding interest in activities at the Medical Center, particularly in the area of cardiac research. Mr. Morris was founder and chairman of the board of Mervyn's retail stores, from the company's establishment in 1949 until his retirement in 1980. The Mervyn's chain includes 50 stores and 12,000 employees.

Mr. and Mrs. Peyton Hawes of Portland Oregon are also longtime supporters of Stanford. Mrs. Hawes is a Stanford graduate and several of the Hawes' daughters have also attended Stanford. Mr. Hawes is an executive officer of Payless Drug Stores Northwest, Inc..

Mr. and Mrs. Gordon Ness of Atherton also have pledged support for the building. Mr. Ness, chief executive officer and chairman of the board of the Stanford Scientific Corporation, attended Stanford and is interested in the applications of technology to the study of cardiovascular disease.

The Ralph J. Weiler Foundation of Los Angeles has also provided a gift to support the cardiovascular building. Mr. Weiler, who died in 1974, was a Stanford graduate from the class of 1922.

STANFORD—

Faculty members of the department of pharmacology at Stanford University Medical Center Monday expressed opposition to the proposed aerial spraying of the pesticide Malathion over 120 square miles of Santa Clara County.

In a letter sent to the mayors of the 14 affected Santa Clara County cities and Congressman Peter N. McCloskey, they said they had "serious reservations" about the plan, proposed last week by federal and state officials, to combat the Mediterranean fruit fly by spraying the county six times using low-flying airplanes.

Malathion kills by inhibiting an essential enzyme in the nervous system of all animals, not just the fruit fly, the scientists said.

"It will, for instance, also kill bees, any possible natural predators of the fruit fly, and predators currently being used in ongoing pest control programs," they wrote.

"The effects on the natural ecological balance cannot be predicted."

Moreover, although once it enters the blood stream of humans and other mammals, Malathion is rapidly rendered harmless--at least in its ability to inhibit the essential nervous system enzyme, it may not be free of adverse effects, they said.

"In particular, irritations could result from Malathion droplets landing on the skin and eyes. Inhaled droplets might cause complications before being detoxified.

"Lastly, we do not have enough information on possible carcinogenic (causing cancer)or teratogenic (causing birth defects) effects of Malathion, but we feel that caution is warranted in the use of a chemical as reactive as Malathion," they wrote.

They concluded that "the fact that human health may be jeopardized and beneficial insects will be harmed is reason enough for considering other strategies for combating the fruit fly."

The letter was signed by Helen M. Blau, Ph.D., Avram Goldstein, M.D., Dora B. Goldstein, M.D., Sumner M. Kalman, M.D., Tag E. Mansour, Ph.D., Gordon Ringold, Ph.D., Howard Schulman, Ph.D., and James P. Whitlock, Jr., M.D.

STANFORD—

When Jimmy Carter visited Portola Valley last summer, Stanford student Buzz Price was told he'd be responsible for coordinating a transport should anything happen to the President or members of his family.

Price was the dispatcher on duty that day at the state-funded Northern California Perinatal Dispatch Center, which operates in tandem with Stanford's Department of Critical Care Transport.

For students, the Center is a quiet place to work.

Except when the phone rings.

That's when the drama begins. The dispatcher, who's a student if it happens to be evening, night or weekend, must coordinate all necessary communications relating to medical and transport arrangements. Perhaps a critically ill newborn needs a bed in an intensive care nursery immediately, and several in the area are full at once. Or a high-risk maternity patient requires prompt hospital attention.

A referral—the acceptance of a patient into a specified facility—should usually be accomplished in less than 20 minutes, says Alvin Hackel, M.D., associate professor of clinical anesthesiology and clinical pediatrics, and director of both the Dispatch Center and the Medical Center's department.

The dispatcher must be prepared for anything. He or she must know where to refer calls, have information handy on airplane and ambulance companies, be competent to deal with all kinds of questions and details, and above all be able to think clearly under stress in emergencies.

"Everything must be mobilized," says Hackel of activities at the Center, which in order to expedite referrals from community hospitals to regional centers on an emergency basis, keeps track of bed availability throughout Northern California.

Utilizing radio communications, dispatchers provide necessary links between hospitals and the often-used "transport team." The team consists of specially trained doctors, nurses and respiratory therapists from the admitting hospital's I.C.U.

Currently the office employs seven student dispatchers, two of whom go to Stanford. They are Price and Heidi Hedlund. Stanford students generally get "first shots" at the odd-hour jobs, says Hackel, and it doesn't matter what their fields of study are. Whether pre-medical or romance languages, "They just have to be committed to this," he says.

Price agrees. An undergraduate in industrial engineering, he didn't really know what the job would entail when he first applied, over a year ago. "I just needed the money," he recalls. At the job interview, however, he became very enthusiastic, and today he says, "It's gratifying to do a job that's important."

-more-

Dispatchers are trained on the job, through the use of tapes and one-on-one teaching by administrative assistant Tricia Robertson and Price, who's been there longer than the other students. During the training period, says Price, the new dispatchers are drilled on protocols for all types of transports. They receive instructions on the equipment and descriptions of their duties, and they are timed through simulated transport arrangements. Dispatchers are required to consult with their supervisors until they complete training, which can last over a month.

The students each work 20 hours a week on eight-hour shifts. On weekdays they work from 4:30 p.m. to midnight or from midnight to 8 a.m. On weekends they also work the 8-to-4 daytime shift. Who gets which shift? "We were all hired for our vast flexibility," says Price. Robertson points out that there is time for studying on the job too, since the workload is erratic. So far Hackel is quite pleased with the performance of students as dispatchers, who he finds have many of the skills required to do the job.

In a 12-month period from September 1, 1979, through August 31, 1980, the Stanford transport team conducted 527 transports of newborns, pediatric, adult and obstetric patients. During that same period of time, the Dispatch Center handled a total of 3,664 referrals, consults, transport arrangements and air-to-ground communications.

Hackel anticipates an increase of at least ten percent in the total number of transports performed in the coming year. This estimate is based on the projected opening of the new intensive care nursery, the gathering momentum of the educational Perinatal Outreach Program, and increased use of the transport program in returning patients to community hospitals for continued care.

STANFORD—

A new class of drugs known as "calcium antagonists" shows promise in dramatically improving treatment for many patients with cardiovascular disease, according to a Stanford University cardiologist.

More than half of a group of patients with documented severe and frequent chest pain (variant angina pectoris) experienced complete freedom from pain while receiving one of these drugs, diltiazem, according to results of the Stanford study published in the December issue of the *American Journal of Cardiology*.

"Diltiazem appears to be a highly effective drug for controlling the pain caused by coronoary artery spasm," reported Dr. John Schroeder, associate professor in cardiology at Stanford University School of Medicine. These are the first published results from a randomized, controlled, double-blind study testing a calcium antagonist drug, Schroeder claimed.

His colleagues in the study were Dr. Steven Rosenthal, Dr. Robert Ginsburg, Dr. Donald Baim, and Irene Lamb, R.N..

Only recently recognized as an important cause of severe chest pain and sometimes even fatal heart attack, a coronary artery spasm is a temporary constriction in one of the major blood vessels serving the heart, Schroeder explained.

Like the more widely known problem of atherosclerosis (a buildup of cholesterol inside the artery) which has, until now, received most of the blame as a cause for angina and heart attack, a coronary artery spasm impedes the flow of blood to the heart muscle. The spasm may occur during activity or at rest, in a cholesterol-blocked artery or in a clear one, Schroeder noted.

Coronary artery spasm may significantly contribute to the pain of angina pectoris in as many as one third of the estimated one million new patients per year in the U.S. who develop angina pectoris, he added.

"Calcium antagonist drugs such as diltizaem are thought to block the inward movement of calcium into muscle cells of the coronary arteries," Schroeder explained.

more-

On slowing the calcium movement, the muscle cells contract less readily and the spasm problem diminishes in many patients, he said.

None of the calcium antagonist drugs has received approval from the Food and Drug Administration yet, Schroeder noted, because clinical tests of the drugs are not completed. However, no side effects were observed from the drug given to participants in the Stanford study, Schroeder said.

Although there are drugs already available, such as nitroglycerine, which can relieve pain caused by coronary artery spasm, it is preferable to prevent the spasm from occurring, said Schroeder, thereby reducing the danger of heart damage or heart attack.

"It is important to have techniques for determining which angina patients have a coronary artery spasm problem," Schroeder noted. "Now we have a way of preventing pain and possible damage from spasm instead of treating the pain after it has begun."

The patient's electrocardiogram, a routine measurement of the heart's beating pattern, displays a characteristic shift when a coronary artery spasm occurs, Schroeder noted.

But since the shift is only seen in patients with an ongoing spasm, the diagnosis is difficult in certain patients such as those who experience angina infrequently or only at night.

In the Coronary Artery Spasm Clinic at Stanford Medical Center, Schroeder and his colleague, Dr. Robert Ginsburg, have devised a method for confirming the occurrence of spasm in these patients.

The patients are taught how to transmit their electrocardiograms over the telephone with special equipment, as soon as they feel the pain begin. The electrocardiogram can then be analyzed at the clinic for the telltale traces of spasm.

Calcium antagonist drugs other than diltiazem are also being tested at the Stanford Spasm Clinic in patients whose chest pain is resistant to usual treatment, Ginsburg said. These drugs include nifedipine, perhexilene and verapamil.

About 15 patients are seen each week in the Clinic, he noted, and the number is rising as the significance of coronary artery spasm in heart disease becomes more widely recognized.

Schroeder's study was supported in part by Marion Laboratories, the drug firm that is seeking Food and Drug Administration approval to market diltiazem in the U.S..

STANFORD—

A step down can be a step forward for someone like Dr. Helen Blood.

Blood plans at the end of this year to relinquish the chair of the Division of Physical Therapy, a post she has held for ten years, in order to shift her main focus from administrative responsibilities to teaching and research endeavors.

"It is my own personal choice that I want to get on with new activities at this time," says Blood. She intends as one of her new projects to work with elderly persons in their societal environments, distinguishing major physical factors that downplay their meaningfulness in the community.

Blood has been associated with Stanford for many years, in capacities diversified enough to afford her a multiple perspective on the Physical Therapy program.

Starting as a student in Stanford's post-baccalaureate Physical Therapy program, she received her Certificate of professional qualification in 1947. Ten years later she returned as a teaching fellow and master's degree candidate, and completed her M.A. in 1959. In 1961 she joined the faculty, having been enticed back to Stanford by the appealing prospect of establishing a professional relationship with professors she had valued as a student.

"This is an exciting campus," says Blood, reflecting on her years at Stanford. "I like the character of this school—I mean the University as a whole, as well as the Physical Therapy program." In fact, the Division has participated in several inter-departmental activities throughout the University, and plans to increase such involvement in the future.

This concept of wholeness has always been important to Blood, whether in regard to educational pursuits, professional alliances or patient care. Her extensive list of publications, her organizational involvements (of which her contributions as a member of the American Physical Therapy Association have been most significant) and her many research projects exemplify Blood's commitment and concern for what she calls the "totality of the patient's life," which includes physical condition along with psychological, social and economic problems. Stanford, says Blood, has been one of the leading schools in emphasizing this concept, while she personally has been a major contributor in the field because of her pioneering efforts to combine these components.

One of Blood's first faculty responsibilities at Stanford, in 1964, was to initiate a three-year home program in San Jose, affiliated with the Visiting Nurses Association, in which students participated in the home care of physically disabled people.

From 1971 to 1978 Blood was involved in Stanford's Family Focus Project. A transitional care unit was set up, allowing family members to spend the final three days of hospitalization with the patient, while they learned techniques of patient care.

Again stressing social and psychological factors, Blood contends that if one spouse, for example, has always been the dominant decision-maker, it is inappropriate for health professionals to arbitrarily decide, "You're no longer going to participate in decision-making because you've had a stroke." Instead, possible role modifications should be explored, she says.

Another important project carried out by the Division from 1974 to 1976 was a cancer rehabilitation program designed to examine the psycho-social barriers which inhibit optimum patient care, and to challenge the common assumption that cancer is strictly a dead-end, terminal experience. The primary purpose of the program was to get regional schools in the western part of the United States attuned to including more psycho-social considerations in their curricula, applicable to cancer and, ultimately, all other kinds of patients.

-more-

Thus important work lives on, even when the research grant money runs dry. "When grants are finished we take the important concepts that have evolved and integrate them within our curriculum," says Blood. "So projects are on-going in a sense, by virtue of impacting both the educational system and the administrative facilities in which we work."

The Division of Physical Therapy is currently involved, under Blood's direction, in a five-year training program for cross-cultural screening of children.

Affiliated with the Well Baby Clinics of the Santa Clara County and San Francisco County Health Departments, the program's purpose is to analyze cultural characteristics which impact health care and early developmental processes, including sitting, crawling, walking and talking.

In some cultures children are placed on the floor, explains Blood, while in others they are not. In some clothing is free and easy; in others children are "bundled and snuggled and tightened up so that they have limited freedom."

The group studies pre-schoolers from birth to five years old. "We're trying to understand both physical and developmental—but primarily developmental—disabilities," says Blood.

Blood's obviously diversified interests stem back to her undergraduate days when, at the University of Utah, she majored in physical education, with a combined minor in anatomy and English. Now a Doctor of Education, with a 1976 degree from the University of Southern California, she tries to attract students with varied backgrounds to Stanford's Physical Therapy program.

Students with bachelor's degrees in many different areas enter the program, from the physical sciences and from other majors such as psychology, sociology and French. This mix provides diversity and challenge both, says Blood. And as a result, graduates from the program provide a mix of professionals in the field and show great variety in the places they choose to work, she adds.

"Certainly, to be associated with a program of Stanford's caliber can be nothing but exciting," says Blood. She will continue teaching professional orientation and sharing the advanced study in administration and community health.

Blood's own decision to become a physical therapist was made after she earned her B.S. in 1942, and found herself disenchanted with secondary school education. Having been always interested in the medical profession, she chose physical therapy as an alternative, when economic factors prevented her entry into medical school.

Does she have any regrets?

"The greatest excitement for me is the interdisciplinary relationships with all kinds of health professionals," she says. "If I had had the economic means to do so, would I still have liked to be a physician? The answer is yes. But I have not regretted the fact that I am a physical therapist, because I've been involved in the profession during a very fascinating period of growth and development."

In fact, Blood's recent doctoral dissertation, though it focuses on physical therapists, is meant for application to all health professionals. Entitled "The Role of Institutions of Higher Education in the Continuing Education of Physical Therapists in California," it asserts that the importance of higher education in initial professional preparation should extend beyond that period, and play a continuing role in maintaining professional competence. Blood developed a model curriculum which could be instituted to accomplish these goals, using California schools as a data base for her research.

In line with Stanford's philosophy, the American Physical Therapy Association (APTA) has recently recommended that entry into the profession be at the master's level by 1990. Since the program here already incorporates this notion, the only change being considered is the possible reinstitution of a former program to accommodate post-professional graduate study. "At the present time we do not allow people with physical therapy degrees to enter our program," says Blood.

In her pursuit of ever broader horizons, Blood has traveled to many parts of the world. On an eight-month sabbatical leave in 1977-78, she served as a visiting professor at the Cumberland College of Health Sciences in New South Wales, Australia, and as a consultant in Australia, Japan and New Zealand.

-more-

Have her experiences in these countries affected her work at Stanford? "Obviously, I've incorporated much of the information into my advanced study area," Blood responds.

But she cautions against comparing foreign educational systems with our own. "Education-wise we are at a different stage and in a different channel of development from the other countries. So I brought back less to incorporate within our curriculum than I did to incorporate within our administration and community health area," says Blood.

Blood's many high achievements are reflected in a impressive list of special honors.

Among these are the two highest national awards ever given to professionals in her field: the Mary McMillan Lectureship Award, which Blood won in 1979, and the Lucy Blair Service Award for outstanding professional service, which she won in 1975. At Stanford Blood received the second Lucille Daniels Recognition Award in 1978, voted upon by students in the Physical Therapy master's degree program.

Blood delivered her Mary McMillan lecture, entitled "Account Ability," at a national APTA conference in Atlanta, Georgia. A play on the title's two words, the thrust of the lecture was the necessity of perpetuating modern-day professional accountability, while guarding against the sacrifice of innovation and creativity.

In it Blood stated, "The focus of the health care industry, the patient or client, has been lost in our emphasis on the mechanisms used for serving or caring for the person."

Helen Blood has been legally blind since 1974, with only peripheral vision remaining. She is independently ambulatory, however, and uses magnifying glasses for close work.

Undaunted by her disability, Blood recently spent ten days vacationing in New England with a friend, enjoying the exquisite fall colors. She especially appreciated the White Mountains of New Hampshire.

"It's gotten in *my* way," says Blood of her blindness, "but it doesn't seem to have interfered with the performance of my job; we've made the necessary adaptations, which have allowed me to continue to function as director."

Not sensitive about the issue of her restricted vision, Blood enjoys the company of people and continues to attend "a good many socials."

It's plain to see why she's invited.

STANFORD—

Dr. Thomas A. Stamey, professor of surgery and head of the Division of Urology at Stanford University School of Medicine, is the author of a new book, *Pathogenesis and Treatment of Urinary Tract Infections.*

The 612-page volume has been published by the Williams and Wilkins Company of Baltimore/London. Designed for students and clinicians, the book meticulously describes modern techniques developed at Stanford, and utilized in the investigation, diagnosis, and treatment of urinary tract infections.

Included is practical, detailed information such as how to determine whether the kidneys are involved in the infection, how to sterilize urine and how to prevent recurrent infections.

Various approaches are described, from surgical treatment of the infected site to the use of medications to prevent reinfections. There is also an analysis of the proper selection and effectiveness of a wide range of antibiotics.

During the past 19 years at Stanford, Stamey followed up patients with recurrent urinary tract infections by culturing the bacterial colonization sites between episodes of recurring infections. Men and women of all ages, as well as infants and children, were included so the studies would have a wide application.

These studies have led to a better understanding of the natural history and causation of urinary tract infections.

Numerous examples of surgical cures are included in his book with bacteriological follow ups for more than 10 years. Examples of bacterial persistance are given to serve as a guide in treating individual patients, and there is a major case study of chronic bacterial pyelonephritis.

"It is now possible," states Stamey, "to take any patient with recurrent urinary tract infections and successfully solve the problem."

Surveys have suggested that several million women in the United States alone—some seven percent of all women over 50, approximately one percent of school girls, and about four percent of young women—are victims of such infections. Many more experience urinary infections at some period of their lives.

A general practitioner can expect to see 59 cases of urinary infection per year for every 1,000 patients who visit him.

As for urologists, probably more than 50 percent of the office practice involves the diagnosis and treatment of urinary tract infection.

"Sexual intercourse is undoubtedly the major cause of a precipitous rise in urinary tract infections between the ages of 18 and 24 in recent years," Stamey says.

Urinary infections in males, only one-tenth as common as in females, occur mostly at the two extremes of life.

STANFORD—

"How long wilt thou sleep, O sluggard? When will thou arise out of thy sleep?"

The Bible's Book of Proverbs offered no answer to its questions, but now a Stanford researcher and his colleagues reply that how long someone sleeps depends on the phase of his body clock at bedtime.

How long a person had been awake before he went to sleep, provided he had been awake at least 14 hours, doesn't seem to matter,they say.

Charles A. Czeisler of Stanford's Sleep Disorders Research Center, Elliot D. Weitzman, Janet C. Zimmerman, and Richard S. Knauer of Montefiore Hospital and Medical Center in New York, and Martin C. Moore-Ede of Harvard report their findings in the December 12 issue of *Science* magazine.

Contrary to popular wisdom, body temperature is not always 98.6 degrees. It varies each day in cyclic fashion, in the average person dipping to as low as 97 degrees and peaking at more than 99 degrees.

Scientists are learning that such so-called circadian (from the Latin for "about a day") rhythms are part and parcel of most body processes. The body clock, located somewhere in the brain, controls and coordinates all the various cycles.

The alternation of sleep with wakefulness is an obvious one of the body's cycles. But blood pressure, heart beat and levels of certain hormones have their ups and downs each day, too.

Using the very stable body temperature cycle to track the internal clocks of their test subjects, Czeisler and his colleagues found that the rhythms of body temperature and sleep-wakefulness are coupled to one another.

When their research subjects, who were normal sleepers, chose to go to bed at a time when their body temperatures were near their lowest points, they slept an average of 7.8 hours. When they chose to retire at their warmest, they slept almost twice as long, an average of 14.4 hours.

"The most important factor in determining the length and internal structure of sleep is when we go to sleep, not how long we have been awake beforehand," Czeisler says. "It's not enough to allot eight hours for sleep if those eight hours are at the wrong phase of the body temperature cycle.

"This finding calls for a re-examination of the way scheduling for night duty and shift work is done.

"The shift worker who gets off at 6 a.m. and decides to do a few things before he goes to bed at 11 a.m. may find he can't sleep well. Other than the obvious disturbances caused by screaming children and barking dogs, much more fundamental biological processes are involved. He is trying to sleep at the wrong phase of his circadian timing system."

Czeisler says a very disrupting cycle is the slow rotation shift system--days for a week, evenings for a week, followed by the graveyard shift for a week.

"Constant quantum leaps in schedules like this never allows the internal clock to catch up, since it can only be reset by a small amount each day."

The array of body rhythms is usually orchestrated to act in harmony, kept in tune by the earth's 24-hour light-dark cycle and social cues. If these prompts are not there, or if they are erratically shifted, however, cycles begin running at their own beat, and sometimes fall out of unison.

-more-

"People just don't realize how important regularity in their sleeping habits is," he says. "Hamsters and blowflys whose schedule is shifted by six hours every week in experiments have a 25 percent shorter life span."

In his experiments, Czeisler removed the usual time cues and let the body find its natural rhythm, which for the rock-stable body temperature is about 25 hours.

Each experimental subject lived for up to six months in a specially-fashioned, windowless apartment, and were not allowed access to current newspapers, radio, TV or anything else that might divulge the time of day. Bright-eyed attendants, on random shifts, ministered to a subject's needs 24 hours a day (breakfast would be provided at 11 p.m. if so requested) and so the subject had no idea what the real time was.

Most of the time, subjects, although they predictably developed "free-running," non-24 hour sleep-wake, body temperature and hormonal rhythms, kept their cycles in sync. Routinely, their body temperature began slipping before sleep, was lowest as they fell asleep, and crept back up as they slept.

Sometimes, however, cycles fell out of unison. While the body temperature rhythm stayed near normal, the length of the sleep-wake cycle was anywhere from 30 to 50 hours long. Also, how long a subject slept on any one "night" seemed erratic and unpredictable at first glance.

On closer examination, however, a very regular pattern emerged. When bedtimes occurred at the temperature trough, sleep episodes were normal. The subject always awoke when his temperature was in the process of going back up, usually six to eight hours after bedtime.

However, when a subject went to bed at or after his temperature peak, he slept inordinantly long (one person once slept 20 hours straight.) Apparently, an out-of-sync subject only woke up after his body temperature had slipped to its low and had begun to rise again.

Czeisler noticed also that subjects most often chose to go to bed just after their temperature trough, and that the type of sleep in which dreams are made, rapid-eye movement or REM sleep, would occur earlier and in greater amounts if the person slept at his temperature low rather than his high.

A person out in the world and active can't just take his temperature one day and figure out the phasing of his body clock, says Czeisler. Too many outside factors come into play, such as how much he is exercising, which causes body temperature to rise, and when he is sleeping, during which it falls.

Already Czeisler, however, working with Dr. William Dement at Stanford's Sleep Disorders Research Center, and other researchers at other centers have used what's been learned to treat people who have problems with their sleep schedule.

"These results allow us to begin applying the principles of circadian physiology to sleep processes in man," Czeisler says. "Understanding how these internal clocks work will enable us to develop rational shift-work schedules and methods to minimize jet lag."

STANFORD—

Stanford University Hospital has opened a new Ambulatory Surgery and Treatment Unit on the ground floor of the Hospital.

Although an anticipated 10 percent of the Hospital's minor surgery patients will be readied for surgery here, actual operations will still be performed in the Hospital's operating room suite.

It is open from 6 A.M. to 7 P.M. Monday through Friday.

The unit is divided into two functional areas, a pre-admit or waiting room for patients and a pre-medicated section with five beds for those patients who require some quiet time before or after surgery.

According to Gwen Williams, director of the Hospital's operating rooms and outpatient processing, the unit is geared towards the "well patient who needs minor surgery."

"It is very traumatic for people having minor surgery to be with those having major surgery," she says. "We've tried to physically isolate them from those things traditionally associated with sickness, such as stretchers."

In the new unit, patients can listen to music, browse through magazines or share time with family members prior to surgery. Eventually, says Williams, the unit will be a "one-stop place" where everything from laboratory work to financial clearance will be handled.

Prior to the unit's creation, outpatients were taken care of in the Emergency Room, along with the critically ill. But the trend, says Williams, is to see more patients on an ambulatory basis away from this traumatizing environment.

"The focus in the past," she says, "has been on critical patients. The unit is a way of offering a better physical environment for the outpatient."

Its creation should also cut back on a patient's medical expenses and open up more beds in the Hospital for acutely ill patients.

In the future if there is a demand, says Williams, the number of beds in the unit may be expanded to nine and the unit may operate on Saturdays as well.

STANFORD—

Isabel Hanson's rheumatoid arthritis was so severe two years ago that she could barely eat, poking the food through stiff and inflamed jaws. A walk down the block was an excruciating ordeal. And one of her hands was so crippled, the fingers literally drifted to one side in what she describes as a waterfall effect.

"I'd been to zillions of doctors," she says, "and they all told me virtually the same thing. It's a progressive disease over which there is little control. You'll just have to live with it."

A semi-professional musician, Hanson found the loss of her ability to play the piano intolerable. In one of several suicide attempts, she sat outside her Berkeley home in a hot tub during an electrical storm, hoping to die.

But somehow, she says, she could never really go through with it; the anger inside was too great. And upon her parents' insistance, she decided to see just one more doctor. On Nov. 30, 1978, Hanson came to the Immunology Clinic at Stanford University Medical Center to see Dr. Halsted R. Holman, a Guggenheim professor of immunology.

"I was ready for something new and awful," she admits, "when Holman came in, looked at me, then looked at my records. Suddenly, he just threw the folder down and started yelling, 'Damn it. This disease has been allowed to get out of hand. This is ruining your life. You're a pianist and you can't play...you can barely walk.'

"I had no energy anymore and here was this doctor expressing the rage that I felt. What's more, he was telling me I could get better."

Hanson, who thought she would never walk again, was put on a vigorous exercise program and started on penicillamine, a copper-based drug with a chelation effect (a type of bonding of elements in the blood). Although the drug can cause kidney damage and has other dangerous side effects, she was told if she could tolerate it, the rheumatoid arthritis might go into remission.

Little by little it did.

In fact, today, Hanson can walk up to three miles, swims regularly and just recently began to pick out a few tunes on one of her two Steinway pianos. She has also written a book about her experience called "Outwitting Arthritis", released earlier this month by Creative Arts Book Company in Berkeley.

Of course, to write the book, Hanson needed help with her severely deformed hand. Although ultimately, she had an operation to correct the ulnar drift elsewhere, her initial treatment was received at Stanford's Hand Clinic. A splint, providing joint protection, enabled her to start typing her work roughly a year ago.

"I choose the 'ing' form in the title," she says, "because you can never outwit arthritis once and for all. It is an on-going process. Part of the therapy is not to give in."

-more-

The book contains 33 cases in which people talk about their experiences with arthritis. Its inspiration, according to the author, came in early 1979 when she was feeling so emotionally isolated that she started a support group of her own.

"Well people just don't know what it's like," says Hanson. "It was wonderful to be around other people who were hobbling around the livingroom the way I was... and to talk to people who were interested in what was working for arthritics and what wasn't."

Hanson discovered in her interviews that while some arthritics found gold shots and steroids effective treatments, others were helped by unconventional methods such as acupunture, special diets and bio-feedback techniques.

"I'm very much a creature of Western medicine," says Hanson, "but what I'm trying to say in the book is these alternative methods should not be dismissed. Doctors acknowledge there is such a thing as psycho-somatic illness, what about a psychological approach to wellness?

Hanson's personal battle with arthritis began in 1974 when she was 45 and the youngest of her children was only 8. The family had been snow skiing one weekend and Hanson thought a pebble had lodged in her shoe. Although she kept shaking the shoe, the sensation remained.

"It was the first awareness of pain I've ever had," she says. "I'd always been a super healthy person before all this happened."

Eventually, other joints in her body began to be affectd and Hanson admits, she began to get scared. In between those early consultations with doctors, she herself tried acupunture, then later a special diet that had little effect on the arthritis, but made her anemic.

By the time she reached Stanford, the most demoralizing event of each day was waking up to a new pain in still another part of her body.

At Stanford, however, she says she received not only the emotional validation she needed to go on, but also the drug that finally worked.

Because of her success in containing the disease, Hanson often speaks on arthritis in the Bay Area whenever she can. She also plans to begin a small problem solving group for rheumatoid arthritics.

"I want to provide a place where they can talk about such things as their sex lives," she says, "or how to disguise your arthritis at work when you're constantly dropping the coffee pot."

She hopes to begin the sessions with two therapists from the University of California in January of 1981.

Meanwhile, Hanson is busy doing the promotional work for her newly-published book.

In a personal copy to Dr. Holman, she wrote the following inscription: "See what happens when you give a patient hope!"

STANFORD—

Dr. Robert G. Petersdorf, professor of medicine at Harvard Medical School and president of the Affiliated Hospitals Center in Boston, will be a visiting professor at Stanford University Medical Center from December 8 to December 12.

Dr. Petersdorf's visit, co-sponsored by the Louis and Dorothy Kovitz Visiting Professorship and the Stanford Community of Internists, has been tailored for the community physician, as well as for housestaff, students and academic faculty.

His professorhip will be highlighted by two lectures.

Dr. Petersdorf will deliver the 10th Louis and Dorothy Kovitz Visiting Professorship lecture as grand rounds in the Fairchild Auditorium at 8:30 A.M. on Thursday, December 11. The talk is entitled "Some Clinical and Experimental Aspects of Bacterial Endocarditis."

His second formal presentation, "Fever of Unknown Origin," will be given at 8 A.M., Friday, December 12, at grand rounds in the cafeteria conference room of the Santa Clara Valley Medical Center.

Besides these lectures, Dr. Petersdorf's week-long visit will include off-campus meetings with community physicians, informal meals with house officers, reports and rounds at Stanford Hospital, Hoover Pavilion, the Veterans Administration Hospital, Santa Clara Valley Medical Center and El Camino Hospital.

Community physicians and Stanford medical staff are encouraged to take full advantage of the numerous opportunities to meet with Dr. Petersdorf, said Dr. Kenneth Melmon, professor and chairman of the Department of Medicine. A detailed schedule can be obtained from the Department of Medicine, S102d, 497-5454.

The Kovitz Visiting Professorship was established in 1969 by Dr. Louis and Dorothy Kovitz of Los Altos to bring outstanding lecturers in medical and surgical fields to the Medical Center. Dr. Kovitz died in 1979.

The Stanford Community of Internists is a recently formed group of community and Stanford faculty associated with the Department of Medicine, which sponsors educational events.

Dr. Petersdorf is well known for his role as a spokesman of academic medicine and as a leader in academic clinical medicine.

Receiving his M.D. degree cum laude from Yale in 1952, he held faculty positions at Yale and Johns Hopkins University before going to the University of Washington School of Medicine in 1960. From 1964 to 1979, he became a professor of medicine in the Harvard Medical School.

He is fellow in the American Academy of Arts and Sciences and a member of the National Academy of Sciences and its Institute of Medicine. He has been very active in the Association of American Medical Colleges, most recently being chairman of the Assembly. He has also served as chairman of the American Board of Internal Medicine and of the National Board of Medical Examiners.

He is on the editorial board of a number of journals and has almost 300 publications.

STANFORD—

A broad patent covering the novel gene splicing and cloning method developed by scientists at Stanford University School of Medicine and the University of California in San Francisco has been issued by the U.S. Patent Office in Washington.

The patent, the first of its kind to be granted in the U.S. in this field, covers the technique only, according to Niels Reimers, director of Stanford's Office of Technology Licensing.

The second part of the patent application filed in 1974 covers products resulting from the use of the technique. It is now pending, but Reimers expects it to be issued within a year as a result of the U.S. Supreme Court's decision last Spring allowing the patenting of biological organisms produced by gene splicing.

The inventors of the gene cloning technique are Dr. Stanley N. Cohen of Stanford and Dr. Herbert W. Boyer of the University of California in San Francisco.

In a paper published by Cohen and Boyer in the *Proceedings of the National Academy of Sciences* in 1973, and co-authored by Annie C. Y. Chang and Robert B. Helling, the first construction in the laboratory of biologically functional DNA molecules that combined genes from different sources was reported.

The scientists constructed these molecules by splicing together segments of two independent genetic elements within the cells of the bacterium *E. coli*, called plasmids, and then inserting the newly constructed DNA molecules into *E. coli* cells, where the recombinant DNA replicated and changed the heredity of the bacterium.

Subsequently, Chang and Cohen introduced genes from the unrelated bacterial species, *Staphylococcus aureus*, into *E. coli* where these genes also expressed biological properties they had displayed in the original host. Shortly afterward, the Cohen-Boyer team showed for the first time that even genes from animal cells could be propagated in bacteria using the DNA cloning methods they had developed.

The propagation in bacteria of genes derived from organisms ordinarily unable to exchange genes with *E. coli* represented a breach in the barriers that normally separate biological species, giving rise to the field of research known as recombinant DNA.

Within months, experiments involving the cloning of bacterial and animal cell DNA from various sources were being carried out in a number of laboratories. These procedures have enabled studies of the organization of complex chromosomes in ways not possible previously.

-more-

They have also made possible the introduction of genes into bacterial cells, enabling construction of bacterial "factories" that can synthesize a variety of biologically produced substances such as insulin, interferon, and growth hormone.

In the past decade, gene cloning has become increasingly sophisticated and the promise of the technique has given rise to a multimillion-dollar gene cloning industry.

Reimers said the method patent just issued by the U.S. Patent Office together with the recent U.S. Supreme Court decision paves the way for the product patent now pending.

"Product claims (for pharmaceuticals and other substances produced by the technique) are generally more significant in patent terms," Reimers said.

"If products made by such technique are not covered, an industry could use the process in another country, then sell the product in the U.S. market without infringing the method patent."

When the product patent now sought by Stanford and UC is issued, licenses will be granted for both patents to industry on a non-exclusive basis for reasonable royalties, Reimers said.

He noted under such licensing agreements, the companies will be required to follow the physical and biological containment procedures of the National Institutes of Health guidelines for recombinant DNA research. Such guidelines are now mandatory for universities and industries which receive federal funds. The rest of the industry follows the guidelines on a voluntary basis, he said.

Patents, under Stanford's patent agreement with the NIH not only encourage investment by companies to make certain that the fruits of research reach the public, but they provide additional income for the university to support research and educational purposes.

In the case of the recombinant DNA method and product patents, both Cohen and Boyer have waved their right to personal royalties.

Reimers cautioned against undue speculation that such patents will result in millions of dollars for Stanford and UC.

"It should be observed," he said, "that at present there is no gene splicing product in the marketplace. Any product developed in the future will have to be tested for efficacy before it is initiated into the Food and Drug Administration process. And a product of a new technology might require a longer period for approval."

STANFORD—

Elliott Levinthal, adjunct professor of genetics at the Stanford University School of Medicine, has been appointed director of the Defense Sciences Office of the Defense Advanced Research Projects Agency in Arlington Virginia.

He will be responsible for research and development activities in the agency's cybernetics technology, materials sciences and nuclear monitoring areas, said Robert R. Fossum, agency director.

Levinthal directed the Medical School's instrumentation research laboratory since 1962. He served as principal investigator on the Viking 1975 lander imaging science team, co-investigator of the Mariner Mars 1971 photo interpretation team, and as a member of numerous committees of the National Aeronautics and Space Administration.

He also served as an associate dean for research in the School of Medicine from 1970 to 1975.

A graduate of the Massachusetts Institute of Technology, and Stanford University, he was formerly president of Levinthal Electronics Products, Inc. when he came to Stanford to direct the instrumentation research laboratory in the Department of Genetics. The laboratory, supported by NASA, was established to design devices which could study chemical events on other planets, including the possibility of forms of life.

Eventually techniques developed for space exploration were applied in the fields of biology and medicine.

More recently Levinthal was associated with the SUMEX-AIM project (Stanford University Medical Experimental Computer-Artificial Intelligence in Medicine).

STANFORD—

Studying growth disorders in children and using microcomputers to monitor the application of anesthesia and the vital signs of critical care patients are among the research interests of the 10 Stanford Medical School scientists selected to receive funds from the Andrew W. Mellon Foundation of New York.

The junior faculty members in basic and clinical sciences have been selected for the 1980-1981 academic year by Dr. Lawrence G. Crowley, vice-president for medical affairs, and acting dean of the medical school in accordance with the three-year $400,000 grant awarded to Stanford University School of Medicine in 1979.

The grant, the third of its kind received from the Mellon Foundation, is meant to "assist in providing teaching and research opportunities for outstanding young faculty investigators." Stanford is one of 15 private medical schools to receive funds from the Foundation.

The recipients are Richard H. Britt, M.D. (Surgery); Dieter Enzmann, M.D. (Radiology); Ronald G. Rosenfeld, M.D. (Pediatrics); James Rothman, Ph.D. (Biochemistry); Peter Rudd, M.D. (Medicine); Peter B. Sargent, Ph.D. (Structural Biology); Howard Schulman, Ph.D. (Pharmacology); Carla J. Shatz, Ph.D. (Neurobiology); Lawrence Steinman, M.D. (Neurology); and Mark Yelderman, M.D. (Anesthesia).

Britt is investigating whether heat, produced by microwaves or ultrasound, can be focused on brain tumors to destroy them. He is also exploring how the structures of certain nerve cells involved in hearing are related to their functions.

Enzmann is exploring whether computer tomography scanning (a new method of imaging using X-rays and computers) can be used to distinguish the stages in brain abscess development. His goal is to make early diagnosis more reliable.

Growth disorders in children is the prime concern of Rosenfeld. He is tracking the levels of two hormones, growth hormone and somatomedin, in the blood of children with growth disorders. In addition, he obtains cells from such children and studies how hormones affect their growth in controlled conditions in the laboratory.

-more-

Each cell in plants and animals has a number of different kinds of membranes, one type surrounding the cell, other types essential parts of cell organelles. Rothman is trying to discover how a cell correctly directs the different sets of proteins, key components of membranes, to the various types of membranes.

Rudd has a multitude of interests. He is trying to establish optimal guidelines for screening hypertension, to devise regimens that will convince patients to more faithfully take their medicine, and to develop effective ways to educate physicians about new cost-effective diagnosis tests.

Sargent studies the formation of synapses, spaces between nerve cells just one millionth of an inch wide. Chemicals released by one nerve cell travel across a synapse to activate or inhibit an electrical impulse in another nerve cell.

Schulman is studying protein phosphorylation enzymes that are calcium-dependent in nerve cells of the rat brain. He is trying to understand how these nerve cells function because they use as their neurotransmitter the chemical histamine, a possible cause of depression.

How cells in the retina of the eye make connections with cells in the brain during development is the subject of Shatz's research. The entire visual system is dependent on information received from the initial nerve connections.

Steinman is studying what happens when the body's defense system, the immune system, mistakenly attacks and destroys myelin, an essential covering of many nerve cells. Antibodies directed against a protein in myelin may be the cause of diseases such as multiple sclerosis and Guillain-Barre's disease.

Yelderman is using microcomputers to monitor the application of anesthesia and the vital signs of critical care patients. This is a less invasive technique than traditional methods.

EDITORS: The following release announces a symposium on nutritional aspects of aging that may be of interest to medical writers, food editors or feature writers. Members of the press are invited to attend, and speakers will be available for interviews on the day of the symposium.

STANFORD—

A symposium on nutritional aspects of aging in America will be held Thursday, December 4 at Tresidder Union on the campus of Stanford University.

Sponsored by the division of gerontology at Stanford University School of Medicine, the symposium will present up-to-date information about nutrition as it relates to human aging.

At the morning session, speakers will discuss the nutritional status of the elderly in America, the changes in nutrient requirements which accompany aging, diets for the elderly, and problems of the aging skeleton.

Workshops are scheduled for the afternoon dealing with special eating problems of the elderly and evaluating nutritional needs of the elderly.

Speakers include Dr. Robert Marcus, assistant professor in gerontology at Stanford, Dr. Barbara Posner, assistant professor in nutrition from Boston University, Dr. Vernon Young, professor of nutritional biochemistry from the Massachusetts Institute of Technology, and Dr. Mary Bess Kohrs, associate professor in nutrition and medical dietetics from the University of Illinois.

The symposium is designed primarily for health professionals who care for the elderly, including nurses, physicians, dietitians and others. Continuing medical education credit is available, and a nominal tuition will be charged.

The Palo Alto Medical Research Foundation, Peninsula Nurses Extended Care Group, and the Mead Johnson Nutritional Division are also providing support to the program.

STANFORD—

When Stephen LaBerge has a dream he doesn't like, he simply changes its content, much the way a movie director might change a scene in a movie.

Through a phenomenon called lucid dreaming, LaBerge, because he's aware he is dreaming, can orchestrate the dream's events—discarding unpleasant characters, rescripting dialogue, even supplying a happy ending.

"Normally, we are not able to exercise choice in our dreams," he says, "because we don't know that we can have control. But in dreams not to our liking, we don't have to fight or flee things that frighten us...even if this is how we usually handle them.

"There are other options—like deciding to step outside our dreams and watch."

LaBerge, who earned his doctorate in psychophysiology at Stanford last June, has been studying lucid dreaming at the Sleep Research Center for the past three years with his colleagues, William C. Dement, Lynn Nagel and Vincent Zarcone.

Reports of lucid dreaming, or dreaming while being fully aware that you are dreaming, are not all that unusual and have been known of since at least the time of Aristotle. And yet, says LaBerge, there has been a theoretical bias against accepting them for what they are.

"The assumption is that the nature of dreams is irrational," he says, "and therefore what these people are experiencing must be day-dreams. We have found it (lucid dreaming) does in fact take place during sleep."

At the sleep lab, subjects who reported having lucid dreams were asked through a prearranged signal to indicate when during sleep they were aware of dreaming. Polygraphs, measuring brain waves, eye movements and muscle tension in the chin as well as the wrists, were used to determine at which stage of sleep this occurred.

What was found, says LaBerge, is that lucid dreams occur almost exclusively during REM (rapid eye movement) sleep, sometimes called active sleep, or paradoxical sleep, because the brain is still as active as when the person is awake.

And yet, adds LaBerge, if the criterion of being awake is whether a person perceives the external world, then the subjects were not, in fact, awake.

Although at this point there are few dreamers who can induce lucid dreams "at will," LaBerge himself has devised a method, which has enabled him to have as many as 26 lucid dreams in one month.

In the January issue of *Psychology Today,* he explains that there are two presleep psychological factors needed for MILD—mnemonic induction of lucid dreams. The first and most obvious, he says, is motivation, while the second is the presleep intention to remember to be lucid during the next dream.

MILD employs both visual and verbal memory techniques to reinforce the ability to perform future actions. This is done, according to LaBerge, by forming mental associations between what one wants to remember to do and the future circumstances in which one intends to act.

When LaBerge wants to have a lucid dream, he says to himself before going to sleep, "Next time I dream, I want to remember I'm dreaming." Then he visualizes himself lying asleep in bed dreaming, and at the same time he sees himself as being in a dream and realizing that he's dreaming.

-more-

Although the events in our dreams are illusory, says LaBerge, our feelings of anxiety and fear are real and must be dealt with, even if we are aware we are dreaming.

"Were it not so," he writes in the *Psychology Today* article, "lucid dreams would have no useful connection in our waking lives."

With a recurring nightmare, for instance, LaBerge says, a person must relive the nightmare in a waking state, conceive of a positive outcome and the next time the nightmare occurs, remember to recognize it as a dream.

"Often if the dream is figured out symbolically in a waking state," he contends, "the nightmare won't come back since the situation we are trying to resolve has been resolved."

By inducing lucid dreams himself over the past year, LaBerge says, he has experienced a significant decrease in the number of anxiety dreams he has had.

Lucid dreaming, by its very definition, means being lucid or in full possession of one's faculties, even though asleep. LaBerge describes the phenomenon more poetically, "The lucid dreamer does not wish to leave the dream world by awakening, but to awaken within the dream."

In so doing, LaBerge believes, the lucid dreamer may ultimately provide first-hand data from within the dream world itself. Even more significant, perhaps, lucid dreaming may open up other spheres of being or consciousness, suggesting, as LaBerge writes, "what it would be like to discover that we are not yet fully awake."

LaBerge often teaches courses in lucid dreaming when he's not at the sleep center. At the moment, he is teaching a course at the San Andreas Health Council.

He is also exploring with his colleagues the healing potential of lucid dreaming under a grant from the Holmes Center in Los Angeles.

A graduate of the University of Arizona with a bachelor of science degree in mathematics, LaBerge was a Woodrow Wilson fellow at Stanford in the late sixties, studying towards a doctoral degree in chemical physics. Although he completed the course work and passed the qualifying exams, he decided at that time to take a leave of absence. He later returned to Stanford, obtaining a degree through the Graduate Special Program.

STANFORD—

A consumer choice health plan, a system of universal health insurance based on fair economic competition in the private sector, has a good chance of being adopted under the Reagan administration, according to Prof. Alain C. Enthoven of the Stanford University Graduate School of Business.

"The Reagan administration," he writes in the Jan. 8 issue of *The New England Journal of Medicine,* "will be under severe pressure to slow the growth of health-care spending at least in the public sector in the coming months."

These costs were about $56 billion in 1975 and $100 billion in 1980, chiefly to pay for the Medicare and Medicaid programs, and not counting the large and rapidly growing tax subsidies to private health insurance.

Noting that only about two thirds of this rise in costs was due to inflation, a health policy group formed to advise President Reagan has recommended giving first priority to a "competition strategy" of health care financing, according to Enthoven. This includes support of "a compromise version of the various pro-competitive bills that can be broadly supported."

Presently five pro-competition bills for reform of the nation's health care system, some based on Enthoven's ideas, are pending before the U.S. Congress.

Enthoven's proposals, described in detail in his recent book, *Health Plan* (195 pp. Addison-Wesley, 1980. $12.95), envision a consumer-choice health plan (CCHP) based on four principles not generally applied today.

These principles, according to Enthoven, are consumer choice, a fixed-dollar subsidy toward the premium of a qualified health-care plan using the same rules for all competitors, and organization of physicians into competing economic units.

More simply stated, CCHP will stress fair competition in the private sector through health maintenance organizations and other alliances in which competition influences cost controls. And it would retain Medicare as an option.

"Most of the criticisms of the consumer-choice plan so far have come from the left, from people who believe that health care should not be in the marketplace," Enthoven says. "Now consumer-choice will come under scrutiny from the conservatives who may want to see more freedom for the market to work."

He notes that until now the health care sector has been regulated to boot, but these controls have failed to contain costs. By elimination of regulation, however, Enthoven does not mean turning medical care into a total free-market process. Few products are bought and sold with no restrictions whatsoever.

What he means by "competition" is the introduction of certain mechanisms into the system to encourage people and institutions to behave differently from the way they have traditionally behaved.

But the "competition strategy," Enthoven says, is viewed to create problems for some. Among them are the teaching hospitals that see themselves threatened.

-more-

He says a recent article by Dr. Eli Ginzberg of the Association of American Medical Colleges, is an example of such negative thinking, spelling out doom for teaching hospitals if "a consumer choice" approach is adopted as a national policy. The reason for the concern is that teaching hospitals, whose job is to train physicians, have higher costs and could not compete with community hospitals.

"In principle," Enthoven argues, "these problems ought to be resolvable through the identification of the incremental costs of teaching and research and through direct public subsidies to support these activities at the level considered appropriate by society."

"The hidden subsidies through Medicare and Medicaid that now support teaching and research," Enthoven adds, "are major contributors to misallocation of resources.

"Dr. Ginzberg and the Association of American Medical Colleges would do well to recognize that the financial pressures on the government are becoming severe. The proponents of the competition strategy did not invent the need for control of health-care costs. It is there.

"The wise course of action for the Association of American Medical Colleges would be to develop its own constructive proposals for cutting the cost of health care in the least damaging way.

"If it does not, costs will be cut in some other way that is not to its liking."

Enthoven believes the prospects of the competition strategy that he advocates are enhanced by a continuing growth of alternative delivery systems, despite resistance by providers and barriers in tax and Social Security laws. HMO membership increased from about 5.8 million in 1975 to 8.8 million in 1979.

If the Reagan administration chooses to implement the competition strategy, what will be the likely steps? Enthoven predicts the first priority will be to work with members of Congress in the coming months to develop a compromise version of the legislation now pending. "This strategy would open up a large part of the market for employees' health insurance to economic competition on a fair basis," he explains.

A second step, according to Enthoven, would be a phased Medicare reform, giving beneficiaries the opportunity to receive more benefits at a lower cost by joining an efficient organized plan.

"Such a change would eliminate vast amounts of unproductive claims-processing paperwork," he says.

STANFORD—

David S. P. Hopkins has been named director of the Office of Analysis and Planning and executive assistant to the vice president for medical affairs at the Stanford University Medical Center.

The appointment of the 37-year-old administrator, effective immediately, was announced Tuesday by Dr. Lawrence G. Crowley, vice president for medical affairs. Hopkins has served as an assistant dean for administration in the School of Medicine since 1978.

In his new position, according to Crowley, Hopkins will be responsible for all analysis and planning activities within the Office of the Vice President including the development of a long range plan for the Center.

Hopkins will coordinate planning activities of the School of Medicine, the Faculty Practice Program and the Hospital.

"A major goal," said Crowley, "will be to assure that planning carried out at the major components of the Medical Center—the Hospital, Medical School, and Clinics—is feasible and compatible with Center-wide goals."

In addition Hopkins will serve as an executive assistant to the vice president for medical affairs, facilitating communications between the VP's office, the three major units of the Center, the University and affiliated hospitals.

Hopkins, a Harvard graduate, holds degrees in statistics and the Ph.D. in operations research from Stanford. He held posts as systems analyst with IBM, the University of California, and was IBM postdoctoral research fellow in the Department of Operations Research at Stanford in 1970-71.

In 1971 he joined the University's Academic Planning Office as staff associate and later became senior staff associate. He is co-author with William F. Massy of a forthcoming book on *Planning Models for Colleges and Universities* to be published by the Stanford University Press.

He is a member of a number of volunteer organizations including the board of directors of the Alan Guttmacher Institute, a research and policy development arm of Planned Parenthood.

In the past three years, Hopkins has been responsible for developing many of the new systems introduced in planning and budgeting in the Medical School. He also contributed to the analysis of the financial feasibility of the Hospital's modernization plan.

STANFORD—

Dr. Richard L. Popp, a noted cardiologist specializing in ultrasound and other techniques for measuring changes in the structures and chambers of the heart, has been named associate chairman of the Department of Medicine at the Stanford University School of Medicne.

Popp, 41, an associate professor of medicine since 1975, is the second faculty member to be named associate chairman of a major department in the School, Vice President for Medical Affairs Lawrence G. Crowley said Tuesday.

"Dr. Popp's appointment reflects the diversity and the heterogeneous responsibilities of the department," said Dr. Kenneth L. Melmon, chairman of the Department of Medicine.

Medicine is the School's largest department, representing 12 academic divisions ranging from cardiology to respiratory medicine.

"It is clear that a single chairman cannot respond in a timely fashion to the various academic and clinical groups that depend on the readiness of the Department's administration," said Melmon.

In his new position, Popp will assist Melmon in day-to-day administration, meeting with faculty, students, community physicians and personnel, and will represent the department on key Medical School committees as needed.

Melmon, in addition to his own research commitments, will assume greater role in the external affairs of the Department, particularly the development of funding sources to support research and clinical programs, development of young investigators, and addition of new programs and laboratory space.

Popp is a graduate of Johns Hopkins (B.A. 1960, M.D., 1964). He was one of the first investigators to recognize the significance of measuring quantitative changes in the structures of the heart. Using ultrasonic waves and a mathematical formula he developed, Popp has been able to measure the internal dimensions of the heart at various phases of contraction.

He has also succeeded in calculating ventricular volumes, stroke volumes and total cardiac output for the heart in normal patients and in patients with heart disease. He has also used the technique to study heart tumors, and effects of drugs and exercise on heart disease.

STANFORD—

Once a woman has lost a breast to cancer, her sense of sexual disability is affected by her husband's perception as much as her own, says Reggie Kriss, a licensed marriage and family counselor on the staff at Stanford University Medical Center.

And yet, one of the major clinical findings during the past year of working with women who have undergone mastectomies, says Kriss, is that too often there is a breakdown in communication, with both partners denying their real feelings.

"We are finding that women are hesitant to talk to their spouses about how they feel," says Kriss, "because they are afraid the mastectomy is turning their partners off sexually. And in fact, this is what is happening."

But at least, adds Kriss, the women she has worked with are venting their feelings, whereas too often their spouses are not.

"I feel the husband sometimes suffers more than the wife," says Kriss, "because he has no one to talk to about how he feels. He may want to be honest with her, but he certainly isn't going to tell her he isn't aroused anymore."

Since the fall of 1979, Kriss has been working with small cohorts or groups of 10 women at a time in a therapy class called "Self-Image and Sexuality: Post-Mastectomy." So far, some 40 women have gone through the one-year program, which consists of 90-minute sessions every week for six months; then monthly sessions for another six months.

At the moment, Kriss is seeking volunteers for two groups beginning in February, which have an optional feature of a couples session. This option, however, comes much later in the program, once the women have become more comfortable with their own feelings.

"The basis of many relationships," say Kriss, "is homeostasis, or keeping things as they are. But the very phenomenon of mastectomy has changed the relationship, even if both partners are burying their feelings.

"It's all very complex, but how is he going to love her body again if she can't."

For the woman, a fear of being sexually unattractive is a "very key point," says Kriss—one that is complicated by the fact that her outward appearance may belie the apprehension within.

"Ideally, a woman may feel that inner beauty is the most important thing," she says, "and yet, when she looks at herself in the mirror, she sees only ugliness. What we try to do is get her to acknowledge the loss of a certain kind of beauty, rather than pretend that the loss doesn't exist."

Kriss considers herself an expert on denial, having denied her own feelings about her first mastectomy for nearly 14 years. Not even her children were aware she had lost a breast until nine years ago when Kriss underwent a second mastectomy and decided, as she puts it, "to come out of the closet." -more-

2-2-2 "I was young and attractive when I had my first mastectomy," says Kriss. "The thought that if people knew they might pity me, was unbearable. Besides, I looked perfectly normal on the outside and no one needed to know how awful I felt about myself under the clothes."

It is this "invisibility" of the mastectomy, according to Kriss, which enables women to hide their fears about their damaged sexuality. But once the initial relief of being alive has passed, she says, the post-mastectomy woman also must learn to cope with an altered self-image.

The function of group therapy, she stresses, is to allow the women to let their feelings out, much the way a Greek chorus tells you what's happening in a play, all the while lamenting the tragedy.

"You have to do a lot of grieving and mourning when you've lost a part of your body," says Kriss. "For a woman,losing a breast is like a man losing his penis. Breasts are a man's first turn on and they are the first expression of a young girl's sexuality—the expression of the so-called female form.

"If sadness and anxiety are not dealt with, obviously sexual arousal is affected."

In developing a program for post-mastectomy women, Kriss and Dr. Helena Kraemer, associate professor of psychiatry at Stanford, spent several months preparing a questionnaire, weeding out those questions they felt might be confusing or unreliable. Ultimately, they intend to use the questionnaire to measure the effectiveness of therapy in rebuilding self-esteem.

An essential part of the existing program, says Kriss, is putting the women back in touch with their own bodies. In one exercise, the women are asked to shower with a fragrant soap, then to rub their bodies with oils or lotions to heighten their sensuality. Later, they are asked to express how they feel.

The program is also a forum for opening up new ideas sexually. The women are encouraged, says Kriss, to be more aggressive or more imaginative in love-making.

Because she herself has come through the experience, the women in the group relate more openly, admits Kriss.

"I always ask my groups whether it helps that I've had one mastectomy. . .or two?, she says. "It always brings a laugh."

Aside from her personal experience, Kriss has led groups of breast cancer patients in the past with Drs. Irvin Yalom and David Spiegel in the Department of Psychiatry. Last year she completed training in the sex and disability unit at the University of California School of Medicine at San Francisco.

A chapter she has written entitled "Sexuality and Physical Disability: Personal Perspectives" is currently in press in an edited edition of a book *Sexuality and Disability* (edited by David Bullard and Susan Knight). The book is being published by Mosby and Co., St. Louis, Mo.

Eventually, Kriss would like to take the women who have worked in her groups and use them as a resource for the "fresh mastectomy" patient in the hospital, both before and after surgery.

"I think this could be a whole new career opportunity for women who have had mastectomies," says Kriss. "Research is helping us find out there are a lot of severe problems that are not being dealt with."

For women interested in the February counseling sessions, Kriss can be reached at (415) 857-0857.

STANFORD—

Dr. Stephen G. Waxman has been named associate chairman of the department of neurology at Stanford University School of Medicine.

The appointment, effective January 12, was announced by Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean of the Medical School.

The associate chairmanship is a new designation and the department of neurology is the first in the Medical School to have such a position.

Waxman, who has been professor of neurology at Stanford since 1978, is also chief of the neurological unit at the Palo Alto Veterans Administration Medical Center (PAVAMC).

According to neurology department chairman Dr. David Prince, Waxman's appointment will strengthen representation of VAMC neurology faculty, students and researchers in the affairs of the department.

"The neurology department has extensive teaching, research and clinical programs at the Palo Alto VAMC which interlock closely with programs based at Stanford Medical Center," Prince explained.

"Dr. Waxman's contributions during the past two years have been very significant in maintaining the high quality of these programs," he added.

Waxman is a leading researcher in the biology of nerve fibers (axons), and an authority on diseases of axons, including multiple sclerosis.

At the age of 35, Waxman is the author of approximatlely 100 scientific papers and abstracts and currently, he directs a major program on nerve disease carried out jointly by Stanford and the VAMC.

A 1967 graduate of Harvard University, Waxman received his Ph.D. in 1970 and his M.D. in 1972, both from Albert Einstein College of Medicine in New York.

Prior to his arrival at Stanford, Waxman was associate professor of neurology at Harvard and visiting associate professor of neurology at the Massachusetts Institute of Technology.

STANFORD—

In a departure from traditional therapy, the Stanford Alcohol Clinic has expanded its scope to include not only alcoholics, but family members who have been scarred by the problem as well.

Most programs, says the clinic's associate director, Dr. Stephanie Brown, will only offer help to family members if they are with the alcoholic.

But at Stanford, even the most distant relative or "a significant other" can receive individual counseling.

The most widely-publicized example, perhaps, is the program for adult children of alcoholics. Many of these patients were so-called model children, who suddenly found their lives falling apart in their 20s or 30s, or sometimes even later in life.

"The general history of these grown-up children we are now seeing is very similar," says Brown. "There is a real syndrome of over-achievement. Often they were the perfect children...yet as adults they are driven and their achievements too often seem hollow."

They also suffer, adds Brown, from an inability to trust their own feelings and perceptions, and a fear of not being in control. These defense mechanisms, developed at an early age to cope with the pain and chaos of an alcoholic household, often backfire when the child turns adult.

In the past, therapists have focussed their attention on the more obviously troubled offspring of the alcoholic, the ones who turn to drugs or alcohol themselves early on. But increasingly, says Brown, professionals now realize that the seemingly well-adjusted child runs an equal risk of alcoholism later in life.

(An estimated 50 to 60 percent of all alcoholics have at least one alcoholic parent.)

At Stanford, there are presently three therapy groups for adult children of alcoholics. Brown, who pioneered the sessions, describes them as a "hybrid of the best psychiatric therapy models and the best of existing alcohol programs."

A clinical psychologist specializing in alcoholism, Brown is mainly interested in the problem of alcoholism as a continuum, or the reasons behind its perpetuation from one generation to another.

"The fact is when you remove the alcohol," she says, "there are a lot of underlying problems. It's important to have treatment available for extra help."

In her work, Brown combines a deeply personal concern with professional expertise. A clinical study of recovering alcoholics, she says, led to a new therapy model, which is being developed at the clinic.

m-ore

"What we are trying to do," she explains, "is design a treatment according to the different stages of alcoholism. One of the biggest problems, however, is that regardless of treatment, the perception of alcoholism tends to be oversimplified."

While the end-stages of alcoholism still carry a stigma, says Brown, anything short of flagrant abuse is not recognized as a problem, since alcohol use is an accepted part of our culture.

"There is no other problem or substance like alcohol. . .so overloaded with other meanings," she says. "It is part of the economics, even the religion in our society.

"Alcohol is everywhere in the most fundamental way."

And yet, adds Brown, there is a cultural importance attached to the ability to control one's self, compounding the problem.

"My personal opinion," she says, "is the reason so much importance is put on control is that everyone would like to think controlled drinking is possible. But I don't see it. The only real treatment is abstinence."

At the clinic, according to Brown, most of the people who come for help have their lives intact, but realize alcohol is no longer working for them and they are worried. This is the first step, Brown believes, in dealing with an addiction.

"Once you have determined that you have lost control," she says, "then you can seek outside help for yourself."

The staff of the Alcohol Clinic is small, with Brown the only full-time staffer. In addition, there is a psychologist, a psychiatrist and an education coordinator, all of whom work part-time.

Funding for the program comes from the Thomas and Katherine Pike Foundation as well as the Mary Pike Foundation. In addition, a new grant from the National Institute of Alcohol and Alcohol Abuse (NIAAA) will provide training for medical students and psychiatry residents in the field of alcoholism.

Brown is extremely enthusiastic about the new program, which she will be teaching.

"Nobody has any easy solutions," stresses Brown, "but through continued clinical research, we are constantly learning new ways to approach the problem."

STANFORD—

The thumb-walk, the elbow chop and the heel-toe dance are just a few exercises designed to help people with arthritis. In fact, though many don't realize it, there are numerous things they can do to help themselves.

A series of free classes in arthritis self-management, co-sponsored by Stanford and the Mid-Peninsula Health Service, aims to drive the point home. The only prerequisites for attending the course are that one be at least 18 and have arthritis.

Part of a patient education research project, headed by research associate Kate Lorig and conducted by the Stanford Arthritis Center, the course has run successfully for two years through series which last six weeks apiece. Dr. Halsted Holman, head of the Arthritis Center, is principal investigator for the project.

Meeting for two hours each week, participants in the class attempt to learn what arthritis actually is. They practice exercises and relaxation techniques, discuss nutrition, medications and patient-physician communication, and generally work on problem-solving for both the physical and emotional aspects of arthritis. They complete questionnaires at several intervals during the course, and are continually compared to a control group of future participants.

Each class is taught by two community leaders who have been trained by Lorig. Currently there are about 60 leaders, ranging in age from 21 to 81, from all walks of life. Many have arthritis themselves or in their families, some are retired health professionals, and others are simply people interested in gerontology.

Ruth Pape, 71, is a former participant and present leader of the course. A retired social worker for Contra Costa County, her background includes assisting physicians with emergency care and teaching Red Cross first aid in Berkeley, Oakland and Contra Costa County. So involvement in health care services is not foreign territory for her.

The research project intends, through the course, to determine whether community health education is effective in terms of quality of life and/or is cost-effective.

As a result of taking the course, do people with arthritis experience less pain and depression? Do they also visit doctors less frequently and take fewer medications, thereby reducing their medical expenditures? And in turn, would such a reduction justify the cost of the course?

-more-

In general, says Pape, participants have less pain than usual while they attend the class. Moreover, if they do feel pain they also feel free to express it, and many knowing ears are eager to listen.

Pape has found the course terrific, though not a cure-all.

"During the class periods I exercise much more and am more aware of diet," she says, admitting that she tends to "slip up" outside of class. Pape is not sure how other paricipants fare once completing the course and on their own. As a leader, she would like to know just how effective the classes are.

Based on initial findings, with 1,200 having completed the course so far, Lorig concludes with some confidence, "People are doing the things we're teaching them and increasing their knowledge." The determination of cost-effectiveness has not yet been established, she says. But the researchers have found that participants experience decreased pain and are more active than before they took the course.

Lorig and Dr. James Fries, assistant director of the Arthritis Center, recently co-authored the *Arthritis Helpbook*, published by Addison-Wesley. It is a self-help book, says Lorig, a "cookbook of all the things people can do for their arthritis." The book is available at the Medical Center bookstore, in local bookstores, and through the Mid-Peninsula Health Service.

Fifteen arthritis self-management classes of about 15 members each are scheduled to begin during the first two weeks of February, at various locations throughout the Bay Area. Participants in the new series will be encouraged to invite "significant others"—spouses, siblings or anyone else who can provide moral support—to attend as well. All classes will be given through De Anza Community College, and credit is available if desired.

To obtain the required application form for the course, or to find out more about teacher training, call 497-7935.

STANFORD—

Stanford University Medical School has recently received a donation of $12,122.27 from the Esther Sparks Cross fund of the California Community Foundation, a publicly supported perpetual trust whose purpose is to solicit and allocate funds for worthy community causes.

To be used for the education of promising and financially pressed medical students engaged in cancer research, the fund was first established at Stanford in 1967.

Founded in 1915, the California Community Foundation is one of the largest community foundations in North America, with active capital funds totaling over $25 million. Its Board of Governors is composed of seven community leaders who are familiar with public needs.

Stanford medical students currently receiving assistance from the fund are: John Ruark, John Oakley, Louie Naumovski, Tien Pham, Dale Kooistra and Doris Burton.

STANFORD—

Does your blood pressure rise during periods of stress at home or on the job? Do you experience unpleasant side effects while taking medication for high blood pressure?

If the answer to either of these questions is "yes", you are invited to participate in blood pressure management training being offered by Stanford University Medical School.

The blood pressure training, which is free of charge, is designed for patients who do not respond well to standard medical treatment, according to Dr. Craig K. Ewart.

The training is part of a research project being directed by Ewart and Dr. C. Barr Taylor.

In recent years researchers at Stanford and elsewhere have begun to use techniques such as relaxation, meditation and stress reduction training to lower blood pressure. Ewart and Taylor are trying to determine if these methods can help those who do not rebpond to drug therapies.

A novel feature of the project, Ewart noted, is inclusion of the patient's spouse or intimate friend in the training.

If the training is to be effective, he explained, the patient must use stress control methods regularly in his or her normal environment.

"It is a lot easier to apply these skills in everyday situations if you have a partner who can help," he commented. "An understanding wife or husband can do a lot to help you reduce the amount of stress in your life."

The six weeks of training is provided to each couple separately, and consists of weekly, hour-long sessions, tailored to the individual needs of each couple.

Sessions will be held in the Stress Relief Clinic.

Persons wishing to participate in the program or needing additional information should call the Stanford Health Behavior Program at 497-5867 weekdays between 9a.m. and 5p.m.

STANFORD—

Dr. Bengt Samuelsson, a 1977 winner of the Lasker Award, will deliver the 1981 Lane Lectures on January 13, 15 and 16 at Stanford University School of Medicine.

Samuelsson, dean of the medical faculty at the Karolinska Institutet in Stockholm, Sweden, is a leading researcher in the field of prostaglandin biochemistry.

Prostaglandins are substances found in the tissues of most mammals and in some of the lower vertebrates and invertebrates. Although all of the functions of prostaglandins have not yet been determined, they are thought to play an important role in a large number of hormonal and neurological activities.

This year's Lane Lectures, the 37th series since the lectureship was initiated in 1896, will be held at 5 p.m. in Fairchild Auditorium at the Medical School. The lectures are open to the public.

Samuelsson's first lecture, on Tuesday, January 13, is entitled "The biochemistry of prostaglandins and thromboxanes." On January 15, he will discuss "Leukotrienes: a new group of biologically active compounds," and on January 16, "Biological roles of prostaglandins, thromboxanes and leukotrienes."

A native of Sweden, Samuelsson received the D. Med. Sci. degree in biochemistry in 1960 from the Karolinska Institutet and the M.D. degree in 1961 from the same institution.

He was assistant professor of medical chemistry at the Karolinska Institutet from 1961 through 1966, professor of medical chemistry at Stockholm's Royal Veterinary College from 1967 to 1972, and returned to the Karolinska Institutet in 1973 as professor of medical and physiological chemistry and chairman of the department of chemistry. In 1978, Samuelsson became dean of the medical faculty at the Instituet.

In addition to the presitigious Lasker Award, Samuelsson has received numerous other awards and honors for his work on prostaglandins. These include the Anders Jahres Award from Oslo University (1970), the Louisa Gross Horwitz Award from Columbia University (1975), the Intrascience Medal (1976), and the Ciba Geigy Drew Award in Biomedical Research (1980).

The Lane Lectures were established in 1896 by Dr. Levi Cooper Lane, one of the founders of Stanford University School of Medicine. (The School was known as Cooper Medical College until 1909 when it became Stanford Medical School. The School moved from San Francisco to the Stanford campus in 1959.)

The Lane Lectures have been given by scientists from around the world who are particularly noted for outstanding achievement and research in medicine. Previous lecturers have included Sir Bernard Katz of University College in London, Dr. George Wald of Harvard University and the late Theodosius Dobzhansky of the Rockefeller Institute.

STANFORD—

Dr. Anne S. Yeager, associate professor of pediatrics, has been promoted to a tenured position at Stanford University School of Medicine effective January 1, the Dean's office has announced.

Yeager, a specialist in infectious diseases, is noted for her studies of pediatric viral illnesses, particularly infections in the newborn.

In 1976, Yeager and her colleagues reported that immunizing children younger than 13 months of age against measles was significantly less effective than immunizing children 13 months of age or older. The researchers discovered that antibodies from the mother still present in the younger children's bloodstreams interfered with the vaccine's ability to confer immunity.

As a result of Yeager's findings, the recommended age for measles immunization was raised from 12 to 15 months in the U.S. and around the world.

Yeager is studying other viral illnesses, inluding cytomegalovirus (CMV) infection, a leading cause of death among premature infants treated in hospital intensive care nurseries. She and her colleagues recently reported that CMV infections, frequently acquired in premature infants through blood transfusions, can be eliminated by careful screening for blood donors who are free of CMV.

Yeager is also investigating the transmission of herpes simplex, a common venereal disease, from mothers to their unborn infants. Neonatal herpes simplex is fatal in over half the infants infected and can also cause severe brain damage in infants who survive. Yeager's work has helped determine the proper medical management for mothers and infants with the disease.

A native of Baltimore, Yeager received her B.A. degree from Cornell University in 1961 and her M.D. degree from Cornell University Medical College in 1965.

She carried out her internship and residency in pediatrics at the affiliated hospitals of the University of Washington in Seattle, and subsequently became a fellow in pediatric infectious disease at the University of Colorado Medical Center in Denver.

Prior to coming to Stanford as assistant professor of pediatrics in 1974, Yeager was assistant professor at the University of Colorado Medical Center and assistant director of the department of pediatrics at the Denver General Hospital.

She has been associate professor of pediatrics at Stanford since 1977, and is currently head of the division of pediatric infectious diseases at Stanford Medical School.

EDITORS: Advance for release A.M. Tuesday, January 5, 1981.

EDITORS: Details follow asterisks. The following release coincides with publication of the December issue of the *Proceedings of the National Academcy of Sciences.* Photos available on request of Dr. Kornberg and his colleagues and of DNA replication proceeding bidirectionally from the replication origin on a plasmid.

STANFORD—

Biochemists at Stanford University School of Medicine have succeeded for the first time in creating a test tube system with all the ingredients necessary to initiate a round of synthesis of the DNA of a bacterial chromosome.

The work is considered important because it is a first step towards discovering how cells control the frequency of DNA replication initiation, a significant event in controlling the overall rate of cell division and growth, the researchers said.

Since the structure of DNA was discovered nearly 30 years ago scientists have unraveled many mysteries of how the molecule replicates to produce identical copies of itself for the next generation of cells. But one crucial problem has remained obscure: how does a cycle of DNA synthesis begin?

Through their new enzyme system, finally the resolution and analysis of factors that control initiation of a chromosome cycle should become accessible, the researchers predicted.

The feat was accomplished in the laboratory of biochemistry professor Dr. Arthur Kornberg, a Nobel laureate who in 1959 created synthetic DNA for the first time, and in 1967 reported the first successful test tube synthesis of DNA that was demonstrated to be biologically active.

Kornberg called the latest achievement "a milestone" in his laboratory's continuing efforts to understand the complex biochemical basis of DNA replication.

His colleagues on the project are Robert S. Fuller, a Ph.D. candidate in biochemistry and Jon M. Kaguni, a biochemistry postdoctoral fellow. A report of their work was published in the December issue of the *Proceedings of the National Academy of Sciences.*

The beginning of DNA synthesis is a key process in the life of a cell, Kornberg explained, because the point at which chromosome replication gets started is the point of commitment, determining whether or not a cell will double its DNA and therefore, whether or not it will reproduce.

Finding how cells control their growth rate could solve some long-outstanding and fundamental questions, such as how cells become transformed, or cancerous. (Rapid, continuous and uncontrolled growth is a hallmark of cancer.)

Understanding the control of DNA replication initation could also explain why embryonic cells synthesize DNA continually and adult cells remain relatively quiescent, Kornberg said.

But at this stage in the research, it's far too early to speculate about what will be found, Kornberg stressed. "If you ask what we can say about major questions of control of growth and cancer at this time, the answer is very little," he said.

"Not only are we not working with animal cells where these questions have been posed, but comparable questions with regard to simpler bacterial cells have not been broached. We don't anticipate any answers until we know a lot more about the details of the system," Kornberg added.

-more-

 Kornberg and his colleagues carried out their work with bacterial plasmids—small circular pieces of DNA independent of the main bacterial chromosome—that were genetically engineered to include the segment of the main chromosome at which DNA synthesis always begins, the so-called origin.

The researchers grew colonies of *Escherichia coli* cells that harbored the origin-containing plasmid, called pSY317. Then they broke open, or lysed, the cells and collected the resulting fluid that was brimming with cell components. But in this rich cell soup, they found that no DNA synthesis was initiated.

"It may not seem reasonable to think that if you start with something inactive, you can then obtain a fraction from it that is active," said Kornberg, "but that's what was done."

By adding just the right amount of ammonium sulfate, a salt that precipitates proteins, the researchers came up with an active fraction.

The amount of salt added is crucial, explained Kornberg—if just a little more is added, an inactive fraction is obtained. By adding the salt, which precipitates certain proteins and other cell components, ingredients necessary for DNA initiation were concentrated or something was excluded that had inhibited initation in the total extract, Kornberg suggested.

The quest to find an active fraction of the bacterial soup in which DNA synthesis could be initiated was an arduous one. "We sought this system for many years," recalled Kornberg, "without success. Many other laboratories around the world were also working very hard on this problem. However, when we found it, the reaction turned out to be much more clear and powerful than we anticipated.

"Initiation of DNA synthesis is actually a rare event—it happens only once in the lifetime of the cell. We are astonished and pleased by the high level of synthesis we have found."

The first attempts to find a system for studying how DNA synthesis begins were carried out using purified proteins known to be involved in the replication of viral DNA, and involved looking for additional factors that would stimulate replication. Only after these attempts proved fruitless did Kornberg's group attempt to extract active fractions from solutions of disrupted bacteria.

Kornberg cites graduate student Fuller's talent and perseverance as "important ingredients" in the lab's latest accomplishment, one that had proved so elusive over many years of hard work.

"Why it took so long to find this DNA synthesis initation system will be answered, in part, by finding out precisely what's in the system that is exacting and irreplaceable," Kornberg said.

"As we sort out the components of this machine, we will learn which elements were absent or defective in previous preparations as compared to the present one. Probably most of our previous failures came about because we were missing several substances in optimal levels. Now we will analyze very precisley, quantitatively, what substances are required.

"The basic processes of synthesizing DNA chains, transcription of this genetic material into the RNA language, and translation of the genetic code into protein are essentially identical in bacteria, plants, animals and humans," Kornberg said.

"For that reason, we have confidence and optimism that understanding these basic processes in bacteria, where research can be done more precisely and easily, will give reliable insights into how these processes occur in higher levels of organisms.

"That there is a universal use of basic biochemical patterns throughout nature warrants our confidence that regulation of these processes, when understood in one system, will become far easier to understand in all systems.

"It is my conviction that the most important elements in understanding the process of chromosome replication initiation will come through knowing its biochemistry," Kornberg added.

The research was supported in part by grants from the National Institutes of Health and the National Science Foundation and by fellowships from the American Cancer Society and the Damon Runyon—Walter Winchell Cancer Fund.

-more-

Placing the *E. coli* origin on a plasmid (using recombinant DNA techniques) contributed significantly to the recent success, explained Kornberg. The origin-containing plasmid used in these experiments was first constructed in Japan by biochemist Dr. Seiichi Yasuda, who later worked in Kornberg's laboratory during the years of 1978-79.

Inserting the origin sequence in a plasmid was really a strategy to enrich for the origin region, which is otherwise a relatively short portion of the *E. coli* genome, occurring just once per chromosome molecule.

It's probably impossible, said Kornberg, using even the most sophisticated techniques, to extract the entire *E. coli* chromosome intact from an *E. coli* cell; it's an intricately coiled string of approximately four million nucleotide base pairs. But a plasmid is a more manageable molecule a few thousand nucleotides long (approximately one-thousandth the size of a chromosome) and it will remain intact when the bacterial cell is broken open.

If the origin were not embedded in a plasmid, trying to locate the sequence, which is only 245 base pairs long (or 1/16,000 the length of the chromosome) would be like trying to find the "needle" in a "haystack" of fragmented pieces from the cell, Kornberg mused. "By placing the origin on the much shorter plasmid, we enriched for it approximately 400-fold," he remarked. "What's more," he continued, "because a plasmid can replicate independently in the bacterial cell, we can obtain as many as 100 copies of the origin, instead of just one, from each bacterial cell."

The new system behaves much like the DNA replication initiating machinery inside an *E. coli* cell. This gives the researchers confidence that their test tube system is physiologically genuine, that it represents the intiation process as it is actually carried out in living cells. For instance, it is knocked out by the same poisons that are capable of blocking initiation in living bacterial cells, and its activity requires the presence of certain genes and enzymes already known to be required for initiation.

Another expectation of a genuine DNA synthesis initiation system is that it would start replication going in both directions from the point of origin—this is known to be the case in *E. coli*, Kornberg said. By examining with the electron microscope origin-containing plasmids from the test-tube system, the researchers confirmed that replication did proceed bidirectionally. This was an added proof that the system was physiologically relevant, they reported.

The eventual aim of this research, Kornberg said, is to characterize the genes and the proteins involved in carrying out and controlling initiation of DNA synthesis. Most likely, several proteins are required, and in fact, some of these are already known. Others await discovery.

And although the 245-nucleotide base pair origin sequence enables replication to begin on the plasmid, "adjacent sequences may be important for more complex behavior expected of the *E. coli* chromosome," Kornberg and his colleagues suggested. Just how the adjacent sequences play such a modulating role will be a focus of study using the new system, they said.

"Ultimately, the exploitation of this system should allow a direct biochemical approach to the regulation of replication," the researchers said. "The availability of an authentic system for the replication of the *E. coli* chromosomal origin should allow the isolation of those factors as well as the understanding of those processes which control the frequency of origin-initiation and couple the rate of chromosomal duplication to that of the cell as a whole."

FOR INFORMATION CONTACT: Lisa Ames (415) 497-6911

STANFORD—

An attractive, slightly overweight teenage girl decides to go on a diet. A familiar scenario so far.

Upon reaching a normal weight, however, she still considers herself fat. She continues denying herself food, to the point of losing up to 30 or 40 percent of her body weight. And yet she can't stop *not* eating.

Food has become the Enemy, her diet an obsession, and the girl a victim of anorexia nervosa.

A psychological disorder which sometimes, though rarely, results in death, anorexia's incidence appears to be on the rise. "Given the tremendous preoccupation with fitness and weight, one would expect it to be," says Dr. W. Stewart Agras, professor of psychiatry at Stanford Medical Center, who answers three or four concerned letters a day from all over the country.

The classic case of anorexia nervosa follows several general patterns, says Agras, though there are exceptions. The typical anorexic tends to have been a high achiever in school—often a perfectionist. Most frequently affected by the disorder are adolescent girls from well-to-do, well-educated families, and the reasons for this are still unknown.

"One could theorize," says Agras, "that weight and appearance are more critical variables in the socialization of young women." Also, studies have shown people (especially women) in upper socio-economic groups to be, in general, thinner than those of other groups.

Many anorexics are sports enthusiasts, though no particular aspirations (such as dancing, acting or modeling) have been definitively linked with development of the disorder. Often, however, being slightly too heavy for the sport she enjoys, the teenager receives pressure to lose weight—pressure from her family, peers, teachers and/or coaches.

The normal conflicts of adolescence also conspire to head certain teenagers towards anorexia, says Agras. Some anorexics fear adulthood responsibilities, and want desperately to control at least one area of their lives. Some are subconsciously rebelling against their parents.

Certainly, says Agras, her family always suffers along with the anorexic. "Besides wasting away, the anorexic disrupts a central family function—mealtimes!"

Parents tend to feel guilty, especially after a series of medical consultations has excluded other possible disorders. Still, says Agras, they often resist treatment of any condition termed a "psychological disorder."

Why would a young woman virtually starve herself? No one knows for sure, though there are several theories about. These cover possible biological, cultural and psychological causes.

Anorexia is a rare disorder, affecting probably no more than one in 10,000, for which some believe certain people are biologically predisposed. But though certain hypothalamic and endocrine abnormalities do occur, the question of whether these are causes or effects of starvation has not been answered. According to Agras, most abnormalities disappear when normal weight is achieved, though conclusive data is still lacking.

"All we can say," he explains, "is that anorexics show all the characteristics of being starved." They always stop menstruating, he adds, often quite early in the disorder. "Other than that, there are no clear biological markers."

Nor are there any clear psychological markers to determine why a particular person is affected, believes Agras, although some disagree with him.

One theory holds, for example, that anorexics are trying to escape from social and sexual pressures of the female role. By thinning down, they may no longer feel threatened by these.

-more-

Other theories point to disturbed and disordered family lives, or maintain that anorexics are manifesting a particular type of neurosis.

While Agras concedes that these all may play a role in the development of the disorder, he emphasizes, "The amount of socialization experience they've lost is probably the major barrier to their future success, and the question is whether they really *can* catch up." He adds, "We don't yet know how to help people regain those lost years."

For the anorexic, weight and body image become overriding concerns. And her body image is often distorted: even when emaciated, she identifies areas of fat. She refuses to resume normal eating, fearing she'd lose control and become very fat.

"Of course that *is* a risk," says Agras. "About ten percent of anorexics do in fact gain large amounts of weight upon recovery."

To lose weight, says Agras, anorexics do anything they can think of. In addition to abstaining from food, they commonly resort to laxatives, amphetamines and excessive exercise.

(In fact, says Agras, some anorexics are first detected when brought in for treatment of injuries—sustained during sports their weak bodies can no longer manage.)

Many anorexics, ironically, enjoy gourmet cooking for others. This is remarkable, says Agras, since they are always hungry themselves. Most reach a stage where they will eat normally—or even binge—but force themselves to vomit afterwards. This syndrome is almost inevitable after a year or two, he says.

Though not affecting one's innate ability, anorexia does reduce scholastic performance. "There's an enormous amount of energy and time that goes into not eating," explains Agras.

"The real problem is the tremendously abnormal social and work lives anorexics lead. Basically they lead lives of chronic invalidism."

Very few anorexics actually die, however, since their weights stabilize after dropping to a certain level. Agras estimates that less than five percent die of starvation and/or medical complications. In fact, many manage barely to survive, even if left untreated.

But if she *is* treated, what's the best method of treatment? The question has sparked much controversy, mainly over behavioral versus psychotherapeutic approaches.

The Eating Disorders Clinic at Stanford is one of several programs across the country which uses behavior modification techniques, says Agras, adding that the clinic deals with obesity and overeating as well as anorexia nervosa.

Psychiatrists Joellen Werne and Barr Taylor currently run the Stanford program, which Agras oversees.

"Here, as at most major medical centers, we see the cases which have failed treatment elsewhere," says Agras. The first priority, he says, is for the patient to gain weight. Until that happens, he explains, it's impossible to begin dealing with psychological problems.

But even before she's admitted, the patient must participate in evaluation sessions with family members and agree to an individually designed, written contract. The contract makes certain privileges contingent upon her gaining small amounts of weight, regularly and steadily during her hospital stay. These privileges may include the opportunity to participate in group meetings on the ward, in physical therapy programs, to watch television, read, and so on.

Obviously, in order for this to work, the patient must recognize her problem and desire help. "I really don't think one can help people who don't want treatment," says Agras, excepting, of course, emergency cases for which medical treatment is vital.

According to Agras, there are three to five anorexic patients staying in the Hospital's two psychiatric wards, at any given time. Since it's a rare disorder, he says, only a few centers of treatment exist nation-wide.

Stanford's inhospital program, which takes an average of ten to twelve weeks, focuses on motivating the patients to eat. "It's very hard work to put on weight," says Agras, explaining that patients must consume up to 4000 or 5000 calories a day before they even begin.

– more

Patients learn to count mouthfuls of food, instead of calories. That's one way they can monitor food intake and gain confidence in their control of the situation. Having them plot graphs of daily weight changes also helps, says Agras, in the system of informational feedback—a clear variable in the program's success.

Reinforcement—through earned privileges and the encouragement of highly skilled nurses, dieticians and therapists—has also proved effective, says Agras. The staff members, he adds, understand and care for the uniqueness of each individual patient. Their concern is to "provide guidelines and gently set limits without becoming like police of an arbitrary or punitive system."

Another technique used is to serve large rather than small meals, based on the finding that anorexic patients generally eat a certain proportion of whatever amount is served.

Once a patient is approaching normal weight, says Agras, she is asked to lose two or three pounds and then regain them. Again, this is to convince her that she *is* in control—a very important step towards recovery.

Also, once on her way up the scale, the patient participates in family, group, and often individual therapy. Besides helping the patient learn to cope, Agras explains, it's necessary to help her family come to terms with a daughter returning to a normal role in the home.

Upon leaving the Hospital, says Agras, patients are encouraged to continue with therapy on an outpatient basis, either at Stanford or with a local therapist.

Long-term results have shown that about 85 percent of the patients do regain necessary pounds. A little over a third of the patients, however, lose weight again, and often return to the inhospital program. Anorexics go through different phases, explains Agras, during which they feel capable or incapable of making progress.

Agras believes inpatient behavior modification is the best current treatment for anorexia nervosa. It's the only method which has been researched so far, he says, with controlled and consistent evidence that it works. Its success is probably due, he feels, to the precise specification of treatment procedures, which facilitates the establishment of new therapeutic programs.

No one has yet experimentally compared behavior modification and outpatient psychotherapeutic approaches to treatment, says Agras. He does not think psychotherapy is as profitable, since it can take months—or even years.

Also, says Agras, weight is not usually the primary concern of a psychotherapist, though there are exceptions. Differing priorities in treatment, he says, form one basis of the controversies which arise.

Is anorexia nervosa a curable disorder? Agras says that some anorexics do recover totally, and for them food is no longer a problem.

But these are in the minority. Most, even after recovery, will always be sensitive to the issue of weight. They may return to normal activities, says Agras, but most former anorexics will always be a bit underweight and have a tendency to relapse during periods of great stress.

Much data and controlled research in the areas of cause, treatment and re-socialization of anorexics is still lacking, says Agras, and sorely needed. He hopes that all concerned fields, including sociology and psychology, will explore the unchartered territory still necessary to our further understanding of this complex and mysterious disorder.

STANFORD UNIVERSITY MEDICAL CENTER
News Bureau Stanford, California 94305

FOR INFORMATION CONTACT: Bobbi Navickis (415) 497-6911
Editors: Pictures available on request if not included. Dr. Linus Pauling's birthday is on February 28.

STANFORD—

Linus Pauling is not a man given to chitchat; he wants to get on with his business, which is "science and the nature of the world."

So as he approached his 80th birthday this week, leaning back in his chair, tugging his black beret down over his nimbus of gray hair, he said a tad wistfully,

"It's interfering a little with my work."

Getting older is not what's interfering, its's all those people interupting him to ask about it, he explains.

When not being the object of an interview, Pauling the two-time Nobel laureate and controversial grand old man of science, was busy directing the Linus Pauling Research Institute of Science and Medicine, writing research papers, lecturing on basic science to a group of clinicians at Stanford and going to parties in his honor.

"I'm busier than ever," Pauling, who from afar looks like a large leprechaun, reports. "Partially because I get hundreds of letters about vitamin C. I try to answer personally all the letters addressed to me. Many are from people with cancer or from their relatives. It's important that they are answered."

He says there are also four or five books he'd like to write.

"The National Science Foundation is hoping I'll write a book on chemical bonds formed by atoms of the transition metals because my ideas here are different from other people's," Pauling, the physical chemist, says.

"And I think more powerful, too," Pauling, the winner of a Nobel Prize for his work on chemical bonds, adds.

"I'd also like to write a book on the molecular basis of life. Back in 1940, I had already developed ideas about this.

"Dr (Ewan) Cameron and I are thinking of writing another book on vitamin C and cancer (the first was published in 1979). I'm also thinking of writing a book on vitamin C and heart disease. Since vitamin C builds up the body, makes people healthier, it can protect us to some extent from all sorts of diseases."

His autobiography?

"I'm always being asked if I won't write my autobiography," says Pauling, who peppers his lectures with enough tantalizing anecdotes to confirm it would be fascinating. "But I have so many other things to do. Hashing over old stuff doesn't interest me as much as making discoveries."

At 80, Pauling transcends the usual description of an active octogenarian as spry. While lecturing, he paces back and forth, clasping his hands behind his back, periodically springing them forward to paint imaginary pictures in the air. In greeting, he thrusts out his hand jauntily. While speaking, he laughs easily, his grin spreading up his pink cheeks to his ears. Always, his mind seems to be racing, thinking, checking that every thought is catalogued and in order.

He seems most tireless in his espousal of the attributes of vitamin C, a subject that has enthralled him since 1966. His advocacy has brought loud howls from some in the medical establishment.

-more-

Pauling is undaunted by the criticism. He's been the target of barbs many times before, he says, "even my theory of resonance." Resonance, a phenomenon having to do with the simultaneous alternatives of how atoms of a compound are bound, is the work of which he says he is most proud. It is a star in his work on the nature of chemical bonds (forces that hold molecules together), which earned him the 1954 Nobel Prize in Chemistry.

In the USSR, his theory came under attack in 1951 because officials thought it conflicted with dialectical materialism principles. But even in the free world, he says, a number of chemists decried it. His theory proved to be right on the mark.

But the attacks on his scientific theories were nothing compared with the attacks on his political stands.

His outspoken anti-war and anti-nuclear testing speeches in the 50s rang out loudly in a country under the hush of McCarthyism.

He was denied a passport in 1951. He was threatened with imprisonment for refusing to cooperate with congressional investigators. He was at least once denied government support on political grounds.

In the very year he won his Nobel Peace Prize, 1962, he and his wife, whom he credits with raising his political and social consciousness, picketed the White House prior to a dinner for Nobel scientists to demand an end to nuclear testing. He protested the Vietnam War before it was politically popular to do so.

Today, he voices alarm about the build up of the defense budget.

"It's real insanity, it seems to me, not to recognize that the existence of nuclear weapons forces the United States and the Soviet Union and the People's Republic of China to get along with one another by peaceful means, to not get involved in war."

One thing not controversial is that Pauling has been a force for over half a century—in the opinion of one writer, with enough "energy, inventiveness, showmanship and genius for a consortium."

His contributions to science are dazzling. He started probing the structure of simple inorganic molecules in the 20s, by the mid-30s he was tackling the molecular structure of the complex molecules of living tissues.

He was among the first to apply the principles of quantum mechanics to the structures of molecules. He introduced into chemistry the concepts of hybrid orbitals (in which electron orbits are moved from their original positions by mutual repulsion), directed valence, electronegativity, and resonance hybrids.

Working with hemoglobin, the major protein of red blood cells, he developed a theory of native, denatured and coagulated proteins. In the 40s Pauling discovered the molecular reason why red blood cells sickle in sickle cell anemia.

In 1940, working with biologist Max Delbruck, he conceived a concept of molecular complementarity in antibody-antigen reactions. He also recognized the importance of hydrogen bonds in macromolecular structures.

He discovered that proteins could be shaped like spiral staircases called alpha helixes. Incidentally and ironically by virtue of his current advocacy of vitamin C, he made this major discovery when he was in bed, felled by the flu. Bored with reading mystery novels, he started folding paper models and discerned the right structure.

He also developed a molecular model for anesthesia, a theory of the atomic nucleus and a theory of memory.

-more-

Now his major interest lies with vitamin C and its affects on health, but Pauling's interests have never been narrow. Last year he published two to three papers each on chemical bonding and on nuclear structure.

His success as a scientist is attributed to his capacity for quick insight into new problems, his ability to recognize interrelationships.

"I have a good memory," he says, "especially for things I'm interested in. And of course, I've been interested in science and the nature of the world. So I have built up and continue to build up a great background of knowledge, largely factual, but also theoretical. When something comes along, I hear something, or read something, that doesn't fit into this picture I have of the world, I start wondering about it, worrying about it, trying to decide whether I need to change the picture, or whether this new report is wrong."

Pauling started building his base of knowledge at Oregon State Agricultural College (now Oregon State University), from which he was graduated in 1922. After earning his Ph.D. from California Institute of Technology in 1925, Pauling went to Europe for two years on a fellowship to work with a number of the physics greats, such as Neils Bohr, Erwin Schrodinger, and William Henry Bragg. By 1927, he was back at Cal Tech, a full professor by 1931. In 1963 he left Cal Tech, and after stops at the University of California at Santa Barbara and at San Diego, he came to Stanford in 1969. In 1973, he started his own institute in Menlo Park (last December it moved to Palo Alto). He is an emeritus professor of Cal Tech and of Stanford.

With his quick mind and his panoply of facts, Pauling has instilled fear in many a scientist that Pauling would beat him to the solution. In *The Double Helix,* James Watson recounts how he and Francis Crick feared that Pauling would figure out the structure of DNA before they did.

For all his showmanship and panache, Pauling confesses to being a shy child.

"In grammar school, I wouldn't represent our school in a spelling contest because I felt so shy. I made an excuse why I couldn't go."

"Only in college did I develop self-confidence and that was because of my scholastic success. I was beginning to be outspoken about my ideas about chemistry. I overcame my reticence. I may have become even sort of brash for a while."

Some would say that Pauling is still being rather brash about his ideas on vitamin C. But Pauling is a total convert. Tucked in a pocket of his blue cardigan sweater pocket are vitamin C pills; he takes 10 grams a day, more when he's sick.

He argues that man is one of the few animals that can't manufacture large quantities of the vitamin. Most animals make very large amounts each day; goats, for instance, make 13 grams a day. And for optimal health, man needs large quantities, he says.

Pauling says that although everything vitamin C does is not yet known, he believes the main way it protects the body from disease is by building up the body's immune, or defense, system.

The jury may still be out on the merits of vitamin C, but the judgment is in on Pauling.

"He has been a pioneer—indeed an activist—not only in the forefront of science, but also in the cause of peace, of health and the alleviation of human suffering," said Nobel laureate Paul J. Flory recently at a Stanford dinner honoring Pauling. "We may not always agree with the causes he espouses, but his dauntless courage, forthrightness and dedication elicits our highest admiration. In this, as in science, he has set an example all of us admire and should emulate in undertaking actions and responsibilities expressing our own convictions."

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

Leah Kaplan, a clinical social worker who has worked at the Cowell Student Health Center since 1964, was recently elected chairwoman of the Board of Stanford's Help Center. She succeeds Bruce Hinchliffe, chairman of the Board from June, 1977 till January, 1981.

Harold K. Boyd, director of the Stanford Medical Fund and associate dean of Student Affairs on campus, was elected vice-chairman.

Kaplan, who currently spends two afternoons a week in the Ombudsman's Office, served as Stanford's assistant dean of Student Affairs from 1974 till 1979. She has supervised M.S. candidates in Counseling and Guidance as well as social workers at the Cowell Center.

Besides working at Stanford, Kaplan, who is married with two children, has served in clinics of San Francisco, San Mateo, Maryland and Connecticut. She has supervised social work students at the University of Calfornia School of Social Welfare. She served on the Board of Directors of the American Civil Liberties Union from 1960 to 1962.

Kaplan has been president of the Stanford Faculty Club since 1980, the same year she won the Lloyd W. Dinkelspiel Award.

She received her B.A. at the University of Minnesota in 1943, and did graduate work at Yale University. She earned her master's degree at Smith College in 1946.

Boyd is a graduate of St. Augustine College, Atlanta University. He received his M.A. in United States history at North Carolina Central University, in 1966.

STANFORD—

Sally R. Agle has been appointed Stanford University Medical Center's deputy director of medical development, a newly created position, announced director of medical development John Ford.

Her appointment effective March 1, Agle will work closely with the director on all aspects of fund raising for the Medical Center.

An associate director of development for the University since 1977, Agle has directed the major gifts program for the East Bay and Monterey regions and coordinated donor relations activities for the entire program.

Previously, Agle worked in Stanford's Office of the General Secretary and in the Hoover Institution. She has also taught at the Instituto Panameno-Norteamericano in Panama.

Born in the Panama Canal Zone, Agle received her undergraduate education at Goucher College in Baltimore, Maryland.

Agle lives in Menlo Park with her husband.

STANFORD—

Three of six fellowships in the neurosciences, awarded for the first time this year by the Esther and Joseph Klingenstein Fund, Inc. of New York, went to young investigators who have been or are closely associated with the department of neurology of the Stanford University School of Medicine.

The awardees, each of whom will receive $99,000 over the next three years, are Dr. Arnold Kriegstein who will join Stanford as assistant professor of neurology in July; and Drs. Jeffery Noebels and Robert Wong, former trainees of Dr. David Prince in the epilepsy research program of the department of neurology.

"We are delighted because three of these awards have gone to outstanding young investigators associated in some way with Stanford Medical School," said Prince, professor and chairman of the department of neurology.

The Klingenstein Fund established the fellowships this year to support investigators working on problems relevant to epilepsy.

"It is an important source of support," said Prince, "which will facilitate training research efforts in a critical clinical area."

In recent years, he noted, federal funding for biomedical research in epilepsy and other neurological disorders has become significantly reduced.

Kriegstein, who received an M.D. and Ph.D. from New York University, worked there on problems of development of the nervous system in a marine animal. He received subsequent training in neurology at Children's Hospital and the Peter Bent Brigham Hospital in Boston.

He will study the development of nerve cells in immature mammalian cerebral cortex and epileptic discharges in the developing brain during his Klingenstein fellowship at Stanford, according to Prince.

Dr. Wong is currently an assistant professor of physiology at Louisiana State University in New Orleans. Dr. Noebels, who received the Ph.D. in neuroscience at Stanford, was subsequently awarded a William Lenox Fellowship by the American Epilepsy Society. He is now completing his medical training at Yale.

STANFORD—

When Romulo Romero examines patients at the Gardner Community Health Center in San Jose he brings to the job his skills as a well trained health practitioner and the personal involvement of a longtime community resident.

Romero, a 1979 graduate of the Stanford-Foothill Primary Care Associate Program, is a physician's assistant at the Health Center, which is located in a Spanish-speaking neighborhood of east San Jose.

"One evening a young man came into the clinic, but would not talk to the nurse," Romero recalls. "It was clear that he felt a language barrier and he distrusted physicians. He finally agreed to talk with me, at first very reluctantly, but opened up and talked more freely once he knew I could understand. I found that he was having sexual problems and some psychological difficulties.

"I feel a special responsibility, as a minority health practitioner, to understand this kind of distrust and to help overcome the barriers," Romero explains.

As a physician's assistant (PA), Romero is not unique—the number of non-physician health care pracititioners (such as PA's and nurse practitioners) is steadily increasing in California and nationwide—but as a minority PA working in a medically underserved community, he is helping fill a vast gap in the health care system, according to Virginia Fowkes, director of the Primary Care Associate Program.

Before entering the Program, Romero volunteered in several community health centers in East San Jose, a neighborhood with which he feels close ties. "I became aware of how there was only one hospital for the burgeoning east side, which is primarily a low-income, high-minority area, while there were many hospitals on the west side," he explains. "Getting more health services to minority areas then became my primary concern."

The Primary Care Associate Program, which was established in 1973, is a two-year training course that Stanford runs jointly with a consortium of community colleges around the state, including Foothill College in Los Altos, Hartnell Community College in Salinas, Modesto Junior College, Bakersfield Community College, and College of the Redwoods in Eureka.

The first year is spent in pre-clinical classroom work at one of these colleges. Clinical work carried out during the second year of the Program is coordinated through Stanford University Medical Center and consists of didactic and clinical teaching at Stanford as well as preceptorship training with a physician in the community.

The Community Outreach Project was initiated last year by the Primary Care Associate Program to recruit minority applicants.

-more-

2-2-2 Compensating for the uneven distribution of physicians and other health care professionals is one of the driving forces behind the Project, according to Ron Garcia, Project director. Even though there has been much discussion about a possible surplus of physicians by 1990, there is little evidence to indicate that those physicians will migrate to the underserved areas or alleviate the health care needs of traditionally underserved populations, he says. And the Graduate Medical Education National Advisory Committee (GMENAC), the same group that predicted the physician surplus, has also predicted that by 1990 the number of PA's needed will increase from the present level of 11,000 to 26,000.

"We look for people, who already are committed to health care professions," explains Garcia. But, unlike Romero, many potential applicants only think of the traditional roles in medicine, such as doctor and nurse, neither of which may suit their needs, Garcia adds.

"Often, we have to make people aware of the many opportunities available to midlevel practitioners," he notes. "Although PA's don't practice independently from a physician, they can handle many medical tasks, such as physical exams, taking medical histories, assessment and management of common acute and chronic medical conditions, treatment of wounds, and health education and counseling.

"In many instances, PA's augment a physician's practice because of clinical or cultural experiences acquired prior to the PA program," Garcia says. "Minority PA's may enable a physician to greatly expand his practice. For example, a Spanish-speaking PA may attract an entirely different population of patients," Garcia says.

George Villanueva, minority recruitment officer for the Community Outreach Project, explains that Romero was an ideal applicant. "We are trying to identify candidates in areas of the state that are medically underserved. These areas frequently contain low-income, high-minority populations. We select applicants from these areas who are committed to returning there when they graduate and go into practice."

To date, 85 percent of the program's minority PA graduates are working in state-designated health manpower shortage areas, Garcia points out.

To help train and encourage students in the Outreach PA program, graduate PA's and physicians who work in minority communities come in frequently to talk about the special health care problems found in medically underserved minority populations.

Romero, who is a part-time clinical instructor in the Program, explains why he takes time from an already hectic schedule to remain involved with PA students. "If I am going to fulfill my goal of improving the quality of health care within medically underserved communities, then I have to help find and train others with a similar social commitment," he says.

The Primary Care Associate program welcomes applicants. To obtain application forms or for further information regarding a career as a physician assistant, contact the Primary Care Associate Program at 703 Welch Road, Suite F-1, Palo Alto, California 94304. Applications for the class beginning September 1981 must be received by March 15.

STANFORD UNIVERSITY MEDICAL CENTER

News Bureau Stanford, California 94305

VACANCY ANNOUNCEMENT

POSITION: SCIENTIFIC WRITER III

DEPARTMENT: MEDICAL CENTER NEWS BUREAU

DURATION: Permanent, Full Time

SALARY: $1632-2077 per month, depending on experience

We are looking for a writer/editor to prepare, edit, and coordinate production of a weekly news supplement on the activities of a large academic medical center complex and its personnel. The supplement is part of *Campus Report*, a weekly newspaper published for faculty and staff of Stanford University.

We will give preference to someone with previous writing and editorial experience in a medical or health-related academic institution.

While the primary responsibility of this job is the newspaper supplement, additional duties will include a variety of reportorial assignments concerning the Stanford Medical Center, its patient care, teaching and research activities, and its personnel; and lending of editorial skills in preparing informational booklets for prospective students and the public.

Qualifications include college degree in journalism or equivalent, three to five years reportorial experience, knowledge of headline writing, and layout and design. Ability to initiate ideas and to produce accurate copy, to work under deadline pressure; understanding of medical terminology and the workings of a hospital and medical center, and willingness to learn operation of word processor.

APPLICATION PROCESS:

Qualified candidates should submit a detailed resume, including salary requirements, and provide representative samples of published material by March 12, 1981 to:

Don Slaughter
Personnel Department-VAC
Serra and Galvez Streets

STANFORD—

Dr. Branimir I. Sikic has been selected to receive a $60,000 two-year Faculty Development Award by the Pharmaceutical Manufacturers Association Foundation (PMAF) of Washington, D.C..

The Awards are given annually to outstanding clinical pharmacologists who are beginning to develop research programs in the field, according to Thomas Hanrahan, president of the Foundation.

Sikic, 33, is an assistant professor of medicine in oncology and clinical pharmacology. He is studying how human tumor cells become resistant to anticancer drugs such as bleomycin, adriamycin and vinblastine.

"A major defense of tumor cells against these drugs appears to be to exclude them from entering and accumulating within cells," he explains. "The cell membrane may be particularly important since some resistant strains of cells are capable of efficiently pumping out these toxic agents."

Using specimens of cancers that have been removed from patients at surgery, Sikic is testing the tumor cells for sensitivity or resistance to drugs in the laboratory. The resistant tumors are then compared to sensitive tumors with respect to their ability to take up drugs, to metabolically inactivate drugs, and to actively extrude them after entry into the cell.

Sikic is also developing resistant strains from sensitive cells by exposing them to the various drugs and selecting for cells which can survive these treatments. The acquired resistance can then be directly compared to the originally sensitive cell population, he explains.

"A novel aspect of this work is the emphasis on studying cells from spontaneous human tumors," Sikic says. "Previous knowledge in this area was derived from animal tumors and cultured cell lines which may have little relevance to the resistance mechanisms of human tumors in clinical practice."

Sikic received the B.S. degree in 1968 from Georgetown University and the M.D. in 1972 from the University of Chicago Pritzker School of Medicine. Prior to joining the faculty at Stanford Medical School in 1979, he was a medical oncology clinical fellow at Georgetown University Hospital in Washington, D.C..

The PMAF Faculty Development Award program was started in 1966 with the ultimate aim of stimulating teaching, research and training in clinical pharmacology, according to the PMAF. Sikic is one of five Award recipients announced this year by the Foundation.

Previous Stanford faculty clinical pharmacologists who have received the award are Dr. Terence Blaschke, now associate professor of medicine, and Dr. Richard Mamelok, assistant professor of medicine.

STANFORD—

Dr. Ronald A. Castellino has been appointed associate chairman of the department of radiology and director of the division of diagnostic radiology at Stanford University School of Medicine by Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean.

Castellino succeeds in both positions Dr. William Northway who has stepped down to devote more time to teaching and research activities.

An associate professor of radiology since 1974, Castellino has been on the faculty at Stanford Medical School since 1968.

In 1970, Castellino became the chief of diagnostic oncologic radiology, a new section which he organized within the radiology department and the first such subspecialty section at a major medical center. For the past two years, he has directed the computerized tomography (CT) body scanning program at Stanford.

Castellino's research has led to improved techniques for evaluating patients with cancer. His research has focused on developing accurate methods for assessing spread of cancer to lymph nodes throughout the body, using radiographic techniques of lymphography and CT body scanning.

Born in New York City, Castellino grew up in Brazil. He received his M.D. in 1962 from Creighton University School of Medicine in Nebraska. He spent two years as a Peace Corps physician in Brazil from 1963 to 1965, and completed his residency in diagnostic radiology at Stanford in 1968 prior to joining the faculty.

In 1974 Castellino was awarded a Guggenheim fellowship and in 1977 he was a member of the U.S. Cancer Delegation to the People's Republic of China. Since 1973 he has been a member of the executive board of the International Society of Lymphology and an associate editor of the journal *Lymphology*. He is the author of more than 100 scientific papers.

STANFORD—

Tom Streithorst, an NBC News correspondent who received a heart transplant two years ago, died Thursday morning (Feb. 19) at Stanford University Hospital.

He suffered a cardiac arrest and physicians were unable to resuscitate him, said Dr. John S. Schroeder, associate professor of cardiology.

Streithorst had been admitted to the Hospital Tuesday night after complaining of feeling feverish, according to Schroeder. He had no signs of rejection.

In addition, according to a recent medical check up, his heart function was normal, Schroeder said.

Streithorst, who lived in San Mateo, had gone scuba diving on the north coast during the weekend, Schroeder said.

The exact cause of death has not been determined pending an autopsy.

The 49-year-old correspondent had gone to work full time for NBC since January 1980 and was based in San Francisco. He had chosen to live close to Stanford where he received a new heart in August 1978, because, as he put it, it increased his odds for survival.

"But I am not afraid of death," he told an interviewer earlier this year. "I'm afraid of sickness, of limitations. You have to take risks to be alive."

William J. Small, President of NBC News, issued this statement:

"Tom Streithorst was a great correspondent, a man of tremendous courage and never failing humor.

"His distinguished career for NBC included some of the most dangerous assignments possible in Vietnam, the Middle East and Latin America.

"He always reported with clarity and insight and never complained about danger. His personal courage in the matter of the heart transplant was admired by all who knew him.

"And his eagerness to return to reporting was no surprise to those of us who were his friends. He will be missed."

Streithorst was with NBC for more than 15 years as a foreign correspondent in Latin America, the Middle East and Vietnam. In 1978, he was told that his heart had given out, and a heart transplant was his one chance for survival. He was accepted in the Stanford Medical Center heart transplantation program, and agreed to let his friends and colleagues at NBC cover his story no matter what the outcome.

-more-

He received his new heart at the age of 47, and his story was telecast on NBC's Prime Time Saturday in August 1979, after a yearlong recuperation. (The story of Streithorst's heart transplant was updated and repeated on NBC in May 1980.)

Streithorst returned to active duty with NBC on January 7, 1980, working out of the San Francisco bureau as a domestic correspondent.

A native of New York, Streithorst was born June 4, 1931 and was a 1953 graduate of Princeton University. He received an M.A. in international relations from Johns Hopkins in 1954.

From 1954 to 1956 he taught history at the University of Beirut in Lebanon. He became the Beirut reporter for *Time* magazine from 1956 to 1958.'

Streithorst joined NBC in 1958 as a Middle Eastern correspondent. He covered the landing of the U.S. Marines in Lebanon under the "Eisenhower Doctrine." He left NBC in 1960 to become a correspondent for *Newsweek* in the Middle East.

Streithorst later went to Brussels, where he covered the Common Market for *Newsweek* and the *Washington Post.*

In 1964, Streithorst returned to NBC as a Latin American correspondent. He was first assigned to Rio de Janeiro (1964-1967), then to Mexico City (1969-1972) and later to Buenos Aires (1972-1975). He traveled extensively throughout Latin America.

In 1973, Streithorst received the Maria Moors Cabot Prize awarded by Columbia University for "distinguished journalistic contributions to the advancement of inter-American understanding."

His Latin American assignment was interrupted three times for duty as a correspondent in Vietnam, in 1968, 1971 and 1972. While in Vietnam during 1968, he was forced to return home for a delicate heart operation.

While in Morocco, in November 1975, he collapsed and was sent back to the U.S. for his second open heart surgery. Placed on permanent disability in 1977, Streithorst moved to New Orleans where his condition worsened and he was told that his only chance for survival was a heart transplant.

Streithorst was married to Alicia Lopez, an architect and a citizen of Argentina. He had three children, Thomas, Catherine and John Michael.

Funeral arrangements are pending.

STANFORD—

Dr. Roger Warnke, assistant professor of pathology at Stanford University Medical Center, has won the first Benjamin Castleman Award of the Massachusetts General Hospital, announced Ronald F. Dorfman, professor of pathology.

The award was designed to honor an outstanding paper in the field of human pathology, published in English in 1980. The candidates, nominated by members of the International Academy of Pathology, were pathologists or pathologists-in-training who had not yet reached age 40. Papers were to be based on human material, with an emphasis on morphological or anatomical approaches.

Warnke's winning paper, "Immunologic Phenotype in 30 Patients with Diffuse Large Cell Lymphoma," was published as a lead article in the *New England Journal of Medicine* (vol. 303: 293, 1980). A collaborative effort by the departments of pathology and oncology, it was co-authored by Stanford Drs. and technologists R. Miller, T. Grogan, M. Pederson, J. Dilley and R. Levy.

Dr. Sanford I. Roth, secretary of the award committee, informed Dorfman that Warnke's paper had won.

The award, consisting of $1000 and a plaque, will be presented to Warnke at the annual meeting of the United States-Canadian Division of the International Academy of Pathology, March 2, at the Palmer House in Chicago.

Warnke received his M.D. at the Washington University Medical School, St. Louis, Missouri, in 1971. He was appointed to a pathology internship at Stanford in July, 1971, and completed his residency—including a postdoctoral fellowship in surgical pathology—in June, 1974.

Warnke was appointed an assistant professor of pathology in July, 1976.

(ADVANCE) FOR P.M. RELEASE THURSDAY, FEBRUARY 12, 1981

STANFORD—

A Stanford University Nobel Laureate Thursday called on fellow academic scientists to resist pressures of "secrecy and gimmickry" sometimes imposed by emerging biotechnology companies.

He also challenged companies now working with university scientists to learn to communicate in a free and open academic manner in order to attract the best scientists and to insure the success of their efforts.

"The explosive developments in genetic engineering have generated confrontations between academia and industry," said Dr. Arthur Kornberg. "Unlike the postwar electronics revolution which originated mostly in industry, the earliest industrial applications of genetic chemistry and immunobiology have come exclusively from academic laboratories.

"Understandably, the scientists that provided the ideas, techniques, and practitioners of genetic chemistry are reluctant to be excluded from its financial rewards by enterpreneurs and venture capitalists."

Kornberg made his remarks in a speech prepared for delivery February 12, at the dedication of the David L. Lawrence Convention Center in Pittsburgh,Pennsylvania.

There are obvious problems, he said, if universities as nonprofit institutions become enterpreneurial and employ their faculties for both academic and commercial performance.

And there are dangers too "if genetic engineering companies appropriate a generation of senior scientists as consultants and junior scientists as employees and seal them off from free exchange of new knowledge."

But the Nobel Laureate noted, "There is no putting this genie in the bottle. For many years we promised applications in genetic chemistry and immunobiology.

"Now when they are within reach we must not circumscribe or blunt them. Solution of difficult social problems that accompany these applications cannot come from summit conferences, nor should we depend on lawyers and government agents.

"I am hopeful that scientists who have been and will remain the major resources of these commercial efforts will have the character and wisdom to preserve academic standards and combat pressures for secrecy and gimmickry.'

-more-

Despite these problems the commercial success of molecular and cellular biology has done two positive things, Kornberg said, "It has created many attractive jobs in an area where opportunities had become scarce.

"Commercial success has also secured a respectability for basic biologic science among our fellow citizens and their governmental representatives, a stature that dominance of the Nobel Prize awards never could achieve."

He added, "What each of us does face and must grapple with is how to shape our scientific lives and cope with a sudden and increasing public awareness and concern with what we do."

Scientists as well as laymen are commonly confused by the distinction between science and technology, Kornberg noted.

He defined science as the acquisition of basic knowledge, and technology as the application of this knowledge to solve a practical problem.

"We recognize that science and technology are interdependent and on occasion inseparable," he said.

"Advances in science depend on technology and have on occasion given science novel directions."

But scientists must always remember that technology is based on a foundation of science, he said. This scientific base is often obscured and ignored when refinements in technology, heaped upon one another,make it seem that the marketed product is more important than the knowledge that fathered it.

Kornberg said: "I believe the responsibility of the scientist is to do the most creative and dedicated research within his or her power, and to report the results honestly, promptly and unstintingly.

"The scientist should also, as a conscientious citizen in a democratic society, participate in the discussions and actions of scientific and social communities.

"It is not the responsibility of the scientist to choose research of clear social or economic value, nor to affect the transfer of research findings to technology.

"The few scientists among us who have the talent to do applied research that bridges the gap between science and technology deserve our applause. But this is a rare talent, as uncommon among great scientists as in the rest."

STANFORD—

A cluster of changes in a person's life, for better or worse, can make that person more prone to sickness, accidents and even criminality, believes Dr. Gurdon S. Pulford, a pediatrician at the Palo Alto Medical Foundation for Health Care, Research and Education, and clinical professor at Stanford.

He is conducting a study in adolescents to see if the frequency and seriousness of illnesses are correlated with the number and types of changes that have recently occurred in an adolescent's life.

"Change itself is important as a cause of disease," Pulford says. "And good events, such as becoming head of the football team, may be as stressful as bad ones."

Stress resulting from too many and too big changes can be a major factor in causing disease, he says. Stress can upset the hormonal balance and alter the workings of the immune system, making someone more susceptible to disease, he explains.

"This contribution is found in all disease, major as well as minor, physical as well as mental, acute as well as chronic, autoimmune as well as neoplastic.

"Life changes for adolescents reach a peak when they are 18, a time when many develop mononucleosis as freshmen in college. This is a disease caused by a virus they may have been harboring for a long time, but which never caused any symptoms before," he says.

He cites an interesting study into the still unknown causes of juvenile rheumatoid arthritis (JRA). Investigators noticed that children with JRA were more than two and one-half times more likely to have parents who were divorced, separated or dead than were comparable children without the disease. And in over half the cases, the divorce, separation, death or adoption occurred near the time the disease appeared.

Even the blame for the number and severity of injuries that high school football players incur can apparently be pinned on, to a degree, too many changes in the player's family life. Pulford tells of another study in which more than 40 percent of the players who had had a death of a parent or sibling, separation or divorce of parents, or more than one of these troubles, were subsequently injured during play. If these events had occurred as recently as the previous year, the risk of sustaining a major injury was up four-fold.

-more-

"Disease may be considered not just the flu," Pulford says. "It's also an unwanted pregnancy, an accident, a theft. Criminality is a social disease."

During the last year, Pulford has asked adolescents coming into the Palo Alto Medical Clinic (now the Palo Alto Medical Foundation for Health Care, Research and Education) if they would fill out a "life event scale," which has been developed by R. Dean Coddington of the Louisiana State University Medical Center.

The scale is composed of 50 of the good and bad turns in life: the death of a parent, getting your first driver's license, loss of a job by your father or mother, being told you are very attractive by a friend, appearance in juvenile court, getting a summer job, and so on.

The 12- to 20-year-olds were asked how many times in the last year each of the scale's events occurred. The more momentous events on the scale are weighted more heavily. Scores have been compiled for each of the adolescents for categories of changes that are considered desirable, undesirable, personal, environmental, and familial, and then a grand total was computed.

About 1000 adolescents are participating in the study, Pulford says.

During the next year, Pulford will score the number of times and the type of illnesses for which the participants return to the clinic. His hypothesis is the more life event changes in the last year, the greater the number of visits for more serious diseases.

If the life event scale does turn out to be an accurate predictor, Pulford says eventually a doctor may be able to say to his patient: "Hey, you've got 400 points this year, be careful."

STANFORD—

Barbara Nichols, the president of the American Nurses Association, will be the first speaker in a distinguished lecture series for nursing, sponsored by the Department of Nursing Services.

Nichols, who is the first black president of the 180,000 member association, will speak on the general topic, "Emerging: Visions of the Future" at a dinner honoring staff IV nurses, Feb. 25, at Rickey's Hyatt House, Palo Alto. The dinner is scheduled to begin at 7:30 P.M.

She will also be at Stanford Hospital all day, Feb. 24, for consultations with administrative groups in the morning, and for open forums with staff in the afternoon.

In addition to her responsibilities as ANA president, Nichols is also director of hospitalwide inservice education at St. Mary's Hospital Medical Center in Madison, Wisconsin. She holds a masters of science degree in behavioral disabilities from the University of Wisconsin, a bachelor of science degree in nursing from Case Western Reserve University and a diploma from the school of nursing at Massachusetts Memorial Hospital.

In 1979, she was awarded an honorary doctor of science degree from the University of Wisconsin-Milwaukee in recognition of her work in health education.

Nichols is currently serving her second consecutive term as ANA president, having been reelected in June of 1980 for another two years.

The next lecturer in the distinguished lecture series will be announced shortly. The Department of Nursing Services plans to hold these lectures every three months during the coming year.

All of the speakers will be national figures, who are leaders in the nursing profession.

STANFORD—

New members and officers of the Stanford University Hospital Board of Directors were announced at the Board's first 1981 meeting Tuesday, February 10. It was also the first meeting of the Board since the Hospital's governing bylaws were amended, expanding both the membership and the authority of the Board of Directors.

The changed bylaws, which went into effect January 1, 1981, were adopted in October, 1980 by the general members of the Hospital Corporation. (The Hospital is a separate, University-owned subsidiary corporation in which the University trustees are also the general members of the Hospital corporation.)

The new Hospital Board of Directors members are Walter L. Arons, M.D., William E. Ayer, Ph.D., Peter S. Bing, M.D., John A. Collins, M.D., Donald Kennedy, Ph.D., Peter J. Levin, Sc.D., William F. Massy, Ph.D., Geraldine F. Steinberg, and David Jordan Stone.

Previous Board members who will continue to serve are Conrad F. Gullixson, Linda Randall Meier, Dean O. Morton, Frank H. Roberts, and Lawrence G. Crowley, M.D..

A final appointment to the Board will be the new dean of the Medical School when that individual is named.

The officers elected for the next two years are Kennedy, chairman; Roberts, vice chairman; and Morton, secretary-treasurer.

Arons is a physician in private practice in Palo Alto, specializing in endocrinology and internal medicine.

Ayer, a trustee of Stanford University, is the founder and past president of the Palo Alto firm of Applied Technology, Inc., now a division of Itek Corporation. He is also a member of the boards of directors of several local and national corporations.

Bing is president of the University Board of Trustees. He has been a member of the Board of Trustees since 1970, and also serves as director of various charitable organizations..

Collins is the Walter Clifford and Elsa Rooney Chidester professor, and chairman of the department of surgery at Stanford Medical School. He is also chairman of the Faculty Practice Plan.

Crowley is vice president for medical affairs, acting dean of the Medical School, and also president of the Hospital corporation. He has been on the Hospital Board of Directors since 1979.

Gullixson, a Palo Alto attorney, was a member of the Hospital Board of Directors from 1962 to 1968, and from 1970 to the present. He served as president of the Hospital Board of Directors from November 1977 to January 1981.

Kennedy is president of Stanford University, and was previously vice president and provost of the University from July 1979 to August 1980.

-more-

Levin is associate vice president for medical affairs and executive director of Stanford University Hospital and Clinics.

Massy is University vice president for business and finance, and professor of business administration.

Meier has been a member of the Hospital Board of Directors since 1978. She is an active volunteer and is on the boards of directors of several local organizations.

Morton, a member of the Hospital Board since 1978, is an executive vice president of Hewlett-Packard Company.

Roberts is a senior partner with the law firm of Pillsbury, Madison and Sutro in San Francisco, and he is general counsel of Standard Oil Company of California. He has been a member of the Hospital Board of Directors since 1970 and was president of the Board from 1971 to 1977.

Steinberg is principal of Enshallah Developments, a corporation engaged in social planning and housing developments. She served as Santa Clara County supervisor from 1977 to 1980.

Stone is an independent oil operator and has been a member of the Faculty Advisory Board, Charles R. Blyth Fund, of Stanford University since 1979.

The newly-amended bylaws, which define more clearly the relationship of the Hospital to the University, give the Hospital Board full authority and assets and distinct boundaries for responsibility and accountability.

The Board's previous authority and responsibility was limited to medical staff matters and to advising the University president on planning, budgets, rates and Hospital needs.

The new Board members reflect the change in composition of the Board specified in the amended bylaws. These changes increase the membership from nine to 15 and specify that 12 of the directors are elected by the general members of the Hospital corporation. Also, the Board must include two general members of the Hospital corporation and seven other citizens who are not employees of Stanford or the Hospital, of whom three must be Palo Alto residents and a practicing community physician.

In addition, the president of the University, the president of the Hospital (the vice president for medical affairs of the University), the Hospital executive director, the University's vice president for business and finance, the dean of the School of Medicine, and the chairman of the Faculty Practice Plan must be among those elected to serve on the Board. The president of the University will generally be elected as chairperson of the Hospital Board.

The changes mark the first time since the inception of the Hospital that practicing physicians—both community and faculty—will serve on the Board.

The Board meets once every two months, while committees of the Board meet on a monthly basis. These include an audit committee, a finance committee, a planning and development committee, and a joint conference committee of the Hospital Board and the medical staff.

STANFORD—

One unique feature of the Palo Alto Veterans Administration renal dialysis unit is its emphasis on care of the geriatric patient. This is because the unit's patient population is, on the average, ten years older than that of other dialysis units.

The unit meshes well with other programs acknowledging "the graying of America" at the Palo Alto V.A. Hospital, one of seven in the country selected by the Veterans Administration to develop a geriatric research and education center. "Studies show that by 1990, two-thirds of all vets will be over 65," says Dr. Robert Swenson, chief of the Artificial Kidney Center at the V.A.

First opened in 1974, the dialysis unit, which contains 12 beds, treats about 75 patients each year, with an average age of 55. At the moment, the oldest is 87 and the youngest 21. With sufficient facilities to accommodate all patients who come for care, says Swenson, the unit turns no one away. The only reason to *not* proceed with dialysis treatment, he adds, would be unwillingness on the part of the patient.

Another characteristic which distinguishes the Palo Alto unit from all others in Northern California, is that half its patients learn to dialyze at home.

"We do encourage but don't insist that patients dialyze at home," says Swenson. "If they know what's happening, they will understand the limitations of the machinery, the limitations of the therapy, and also the virtues and benefits."

One major virtue of dialyzing at home is that costs are kept down—somewhat. Developed as a lifesaver in the mid 1960's, dialysis—which removes small molecules from the blood by simple diffusion—now costs at least $25,000 a year. Patients can save whoever's paying $10,000, by dialyzing at home with the help of a relative instead of a hospital's trained personnel.

At present, 75,000 patients in the U.S. are undergoing dialysis, to the tune of $1.3 billion a year. Under the End Stage Renal Disease Program of 1972, Medicare covers 80 percent of the cost. As the cost of dialysis rises linearly in the U.S., the taxpayers' burden will grow steadily harder to bear, already a cause for concern to many government administrators. For patients who are veterans, however, the V.A. pays the total cost.

Kidney transplants are also expensive, costing about $25,000 each. "We consider kidney transplantation and hemodialysis to be equally efficacious," says Swenson. "But we insist that our transplantation candidates be comfortable with dialysis before the operation, in case the kidney is rejected. With cadaver kidneys, only 50 percent take," he explains.

Diseases which generally result in the need for dialysis are glomerular nephritis in the young, and polycystic kidney disease, kidney disease secondary to hypertension, and atherosclerosis in older people.

Patients initially dialyze twice a week, later increasing to three times as their disease progresses. The process generally takes about three and a half hours each time. (The larger and heavier the person, the longer it takes him to dialyze.)

-more-

A person on dialysis is chronically anemic, his red blood cells at a low ebb. His diseased kidney has stopped making the hormone erythropoetin, which stimulates the bone marrow's production of the cells, and the dialysis machine cannot replace the hormone's action.

As a result, intensity of activity is limited for the patient: he probably couldn't climb a mountain because of low red blood cell level, says Swenson, though some hemodialysis patients do participate in jogging programs.

Uncontrolled hypertension can also limit the patient's physical activity. And for older patients, says Swenson, there are accompanying problems such as atherosclerosis and diseases of old age to contend with.

Diet restrictions are relatively minor, says Swenson, but dialysis patients must limit their fluid and potassium intake, and avoid binge-eating.

Since no portable dialysis units now exist, there are also certain travel restrictions. But patients are free to visit other dialysis centers, located across the country. "We try to break through the patient's idea that he's frozen in this place," says Swenson, adding that the ultimate dependency on machine, doctor and mate often leads to psychological frustrations for the dialysis patient.

The V.A. Medical Center has pioneered the use of high efficiency dialyzers which cut down on the time of dialysis, and computers to monitor chemicals in the blood, making sure the dialysis is sufficient. The V.A. has trained 15 to 20 of all practicing nephrologists in Northern California.

Regularly exchanging patients, staff and faculty with Stanford's dialysis unit, the V.A. unit is a training ground for dialysis technicians (every unit in Northern California has a technician trained at the V.A.), and a clinical testing ground for newer forms of therapy.

One of these, called "continuous ambulatory peritoneal dialysis," involves placing liquid in the peritoneal cavity and allowing diffusion to occur continuously. While it requires neither machine nor helper, this process causes possible infections and is not very efficient, says Swenson, who is pessimistic about its long-term effects.

But research goes on, in a never-ending effort to combat kidney disease.

EDITORS: ADVANCE FOR RELEASE THURSDAY, FEBRUARY 12, 1981.

STANFORD—

Salads and raw vegetables are dangerous foods for certain hospitalized cancer patients to eat, according to a report in the February 12 issue of the *New England Journal of Medicine.*

Many bacteria lurk on fresh salad vegetables, even after washing, and these are known to include types of bacteria that frequently cause life-threatening illness and death in certain types of cancer patients, says the report by Dr. Jack S. Remington, professor of medicine at Stanford University School of Medicine and Dr. Stephen Schimpff, professor of medicine at the University of Maryland School of Medicine.

The problem is most serious for those cancer patients receiving radiation or drug treatment that helps control the cancer but at the same time drastically reduces their white blood cell count. Since the white blood cells are a vital component in the body's defense against bacteria, these patients become extremely vulnerable to bacterial infections while receiving cancer therapy, the doctors explain.

The patient's weakened defenses are unable to prevent food-borne bacteria from invading, and once they colonize the digestive tract, the bacteria may proliferate and spread, causing serious or fatal infection throughout the body.

Most physicians are very fastidious about keeping susceptible hospitalized cancer patients away from sources of airborne bacteria, Remington and Schimpff note, with the use of isolation rooms and through administration of antibiotic drugs.

But ironically, these antibiotics may actually foster, rather than hamper, infections from some of the bacteria commonly found on fresh produce.

Harmless bacteria normally live in peoples' intestines, the doctors explain, and these "friendly" denizens actually do their human hosts a favor by producing noxious substances that discourage virulent bacteria from surviving in the gut.

-more-

However, antibiotics kill a large number of the "friendly" bacteria, thereby permitting antibiotic-resistant strains of the harmful ones to take hold.

About 50 percent of hospitalized cancer patients die from an infection rather than from their cancer, Remington notes.

And "nearly 50 percent of infections in cancer patients have been shown to be caused by hospital-acquired organisms which have colonized the patients' digestive tract," state Remington and Schimpff.

"There appears to be insufficient appreciation of the potential role of food as a major origin of these organisms," state the two researchers, both experts in the area of infectious diseases in cancer patients.

Remington is chief of the division of allergy, immunology and infectious diseases at the Palo Alto Medical Research Foundation, and Schimpff is head of the section of infection research at the Baltimore Cancer Research Program (National Cancer Institute), University of Maryland.

Several independent studies have found that salad ingredients, more than any other foods tested in hospital kitchens, harbor harmful bacteria, the doctors note.

"Physicians must recognize this problem now and deal with it . . . by eliminating salads from the diets of certain high risk patients," they declare.

"The hesitation to limit or prohibit feeding salads to patients stems, in some instances, from lack of prospective controlled studies which doctors feel should be performed before such a practice can be recommended or accepted," the two physicians note.

"But shall we really feed harmful bacteria to these high-risk patients to answer such a question, as is being done now with salads?

"We doubt that prospective, randomized trials are indicated to prove that food, especially salads, serve as a major source of new pathogenic bacteria," they conclude.

STANFORD—

Stanford University is applying to the National Cancer Institute (NCI) for grant assistance to help in construction of a two-story 25,000 square-foot radiobiology research building to be located on Governor's Avenue west of the Medical Center.

Total cost of the new building is estimated at $8.8 million. Federal assistance sought is $2.7 million, while $6.1 million must be found from private gifts.

The application was approved by the University's Board of Trustees on Monday, February 9.

The new facility would be the second building in the Governor's Avenue complex, an eight-acre site set aside by the University in 1973 for a cluster of research buildings. (The Louis B. Mayer Cancer Biology Research Laboratory, the first research facility to be constructed on the site, was dedicated in 1975.)

The new facility will accommodate a variety of research programs all directly related to cancer, according to Dr. Robert Kallmam, director of the radiobiology research division.

They include basic studies on radiation and drug effects in tumors, combined radiotherapy and chemotherapy techniques in cancer treatment, development of radiosensitizers (chemicals that enhance the effects of radiation in cancer treatment), studies of cellular capabilities in repairing damaged genetic material (DNA), and research on hyperthermia (the use of heat in treating certain types of tumors).

In addition to laboratory and office space, the new building also will house a major specific-pathogen-free mouse facility and a special biohazard virus laboratory constructed according to stringent federal safety standards.

The new construction should help alleviate the problems of severely limited and fragmented space the radiobiology program has faced in recent years, Kallman noted.

The present target date for beginning construction is early 1984, with occupancy targeted for late summer of 1985, Kallman said.

Communications with appropriate agencies are under way, and the University has prepared an environmental assessment statement.

STANFORD—

Dr. Maria I. New, chairwoman of the Department of Pediatrics at Cornell University Medical College in New York City and Pediatrician-in-Chief at the New York Hospital, will deliver the eighth annual Katharine D. McCormick Distinguished Lecture on Thursday, February 12.

Her lecture, "An Update of Congenital Adrenal Hyperplasia," will begin at 5 P.M. in Fairchild Auditorium at the Medical School.

Congenital adrenal hyperplasia, a group of inherited diseases, results when any one of a number of enzymes needed to make the adrenal steroid hormones is defective. Because of such a deficiency, the adrenal secretes sex steroid hormones instead of its usual complement of corticosteroids, causing the genitals of both boy and girl infants to develop abnormally.

Studying for over a decade how the adrenal gland functions in both normal and diseased states, Dr. New is an accomplished laboratory researcher and pediatrics clinical investigator.

She has brought about a new understanding of the adrenogenital syndrome. This group of disorders results from excessive or abnormal patterns of secretion of the adrenal steroid hormones, possibly as a result of an adrenal tumor. In the clinic the syndrome most often is seen in women who develop characteristics typical of the normal male, such as a tendency to baldness, a receeding hairline, and growth of a beard.

She also discovered, in pioneering studies, a new metabolic defect responsible for hypertension in children and was instrumental in alerting pediatricians to the problem. She has been active in educating physicians and the general public about new findings in diabetes, metabolic disorders and kidney disease.

The McCormick Lectureship honors Katharine Dexter McCormick, who donated $5 million to Stanford Medical School in 1969 with the expressed wish that it be used "for the encouragement and assistance of women pursuing the study of medicine, in teaching medicine and in engaging in medical research."

Katharine McCormick was a co-founder of the League of Women Voters and a vigorous champion of women's rights.

STANFORD—

Stanford University Hospital is working on a possible solution to a knotty problem concerning patients who are Jehovah's Witnesses.

The problem is how to avoid giving Jehovah's Witnesses unwanted blood transfusions, and at the same time prevent malpractice suits that may result when doctors comply with the wishes of such patients.

Stanford Hospital has an average of three to four Jehovah's Witnesses as patients each year.

One man working on a constructive answer to the problem is San Jose attorney William Hardy, representative of the Watchtower Bible and Tract Society (the Witnesses' legal organization).

Working with Carole Price, assistant director of the Hospital, Hardy has proposed what might be a mutually beneficial solution to an often complex situation.

Hardy explains that Jehovah's Witnesses' refusal to receive transfusions is based on religious beliefs, with scriptural roots. Alternatives to transfusions are acceptable to the Witnesses, but they do not always work.

And the Witnesses feel compelled to live by their principles, says Hardy. "Jehovah's Witnesses believe that God will reward them for being steadfast in their beliefs."

His proposal has the purposes, says Hardy, of building better relationships among hospitals, doctors and Jehovah's Witnesses, and of avoiding court battles which are productive to no one.

In return for *not* performing unwanted transfusions, hospitalized Witnesses and/or their relatives would sign a release to relieve the Hospital of legal responsibility. This would enable adults, explains Hardy, to exercise their right to refuse any medical procedure.

Already provided to many doctors, lawyers and hospitals is a booklet explaining the Witnesses' beliefs. Individuals submit documents to their personal physicians and carry statements in their wallets—signed in the presence of two witnesses—to the effect that they do not wish to receive blood transfusions.

-more-

2-2-2 In addition to the release forms, says Hardy, the Society would provide counselors whom the Hospital could call on in emergencies. The counselors would be instrumental in protecting physicians, by "hearing and seeing what the patient wants," says Hardy.

Hardy recognizes that in cases dealing with children, parents' decisions can be superceded by court rulings, but he hopes that physicians would at least honor families' wishes by avoiding transfusions if at all possible.

Having handled court cases on this conflict for over 20 years, Hardy feels that the ready supply of available blood often makes doctors too hasty in performing transfusions. "During surgery, a good, skilled physician can often prevent the loss of blood in many ways," he says.

The plan Hardy advocates is an attempt to iron out problems on both sides, he says, and to encourage treatment of the *whole* patient—including emotions and religious beliefs.

Hardy says that many well-known hospitals on the east coast have already agreed to the program. He approached Stanford—along with a few other hospitals in the area—because of the cooperative attitude he's found here in the past. Hardy hopes that if Stanford adopts the proposal, other hospitals may follow the lead.

Price has already broached the subject informally with a few physicians, she says, who have indicated an interest in further information. She intends to distribute written material to staff physicians and to actively solicit their views.

Price has identified certain difficult issues in the plan, which require further discussion. For example, what if the patient is unconscious, and his wallet-sized card was signed over two years ago—should it still be valid? There might also be difficulties in cases where the spouse of the patient is not a Jehovah's Witness.

Moreover, the range of possibilities is such that general rules are hard to make, says Price. She emphasizes that what's really important is to fully apprise patients of the risks of the procedure if blood and blood products are not going to be used, in order that they can make well-informed decisions.

One of the benefits Price sees in Hardy's proposal is the fact that physicians would be educated in advance about the Witnesses' beliefs, and vice versa.

Certainly, an advantage of the program, Price adds, would be to identify for the Witnesses those physicians who are willing to cooperate with their wishes.

Dr. William C. Dement, professor of psychiatry and behavioral sciences and director of the Sleep Disorders Center at Stanford University School of Medicine, has received the 1981 Intra-Science Research Foundation Medalist Award for his research in the areas of sleep and sleep disorders.

Dement accepted the award jointly with Dr. Michel Jouvet of the Universite Claude-Bernard (Lyon, France) during the Intra-Science Research Foundation's 14th annual symposium, held February 3-6 in Santa Monica, California.

Dement is widely recognized as an authority in the areas of basic and clinical sleep research. In addition to his contributions to the understanding of sleep apnea, narcolepsy and insomnia, he has been an outspoken proponent of increased scientific research on sleep and its disorders, and he has promoted recognition of sleep disorders as a field of clinical medicine.

Dement is the founder and first president of the Association of Sleep Disorders Centers, editor-in-chief of the journal *Sleep*, and he is chairman of the Joint Coordinating Council of Project Sleep, the U.S. Public Health Service's program on insomnia and sleep disorders.

The Intra-Science Research Foundation of Los Angeles is a nonprofit organization that supports education and research in the health sciences. Each year the Foundation sponsors a symposium in a selected area of biomedical research, and honors outstanding researchers in the field with the Foundation's Medalist Award. Dement's award represents the first such honor to be given to a sleep researcher.

A previous Stanford University Intra-Science Medalist Award winner is Dr. Carl Djerassi, professor of chemistry, who received the award in 1969.

The Foundation's 1981 symposium, "New Perspectives in Sleep Research," is being held February 3-6 at the Miramar Sheraton Hotel in Santa Monica.

Sessions include such topics as the pharmacology of sleep control, sleep in old age, dream psychophysiology, and biological rhythms.

STANFORD—

It's often painful for a child, or even an adult, to be physically different. Tall or short, fat or skinny, people will have some derisive remark to make.

Like other physical aspects, height is primarily a product of heredity. If you are short, your ancestors were probably short too. Occasionally a chronic disease can be responsible for decreased growth. Or sometimes people are small because they lack growth hormone.

There are about 1.8 million very short children in the U.S. below the third percentile in predicted height. About one percent, or 18,000, of these children are deficient in growth hormone.

Doctors can supply that growth hormone to children who are deficient to help them reach normal height. But how many of these children are treatable by the hormone or how it works are still matters of scientific debate.

For example, researchers at Emory University in Atlanta recently found that even children with seemingly normal levels of growth hormone yet nevertheless short (perhaps 40 percent of the short children) could also be made to grow when given growth hormone.

The problem with determining precisely which children growth hormone can help has been its short supply. The hormone has been extracted from the pituitaries of human donor-cadavers. Its supply has been strictly regulated and available from the National Pituitary Agency (NPA).

Its supply has been so scarce that growth hormone was only given until a patient reached a height of five feet. That was all the NPA would provide.

Growth hormone acts primarily on bone, cartilage and muscle although it also affects other organs such as the kidneys, liver, and intestines. To treat one child for one year, 50 pituitaries from cadavers are needed, with an average treatment lasting 5 to 10 years.

That is why the manufacture of large amounts of working growth hormone made by genetically-engineered bacteria has been greeted with great excitement by the medical community. For the first time all the potential benefits of treatment as well as other uses will be studied in detail.

The South San Francisco firm Genentech, Inc., one of the leaders in the biotechnology industry, has manufactured the hormone, and the first in a series of clinical tests to determine its effectiveness and safety have begun in the division of pediatric endocrinology of the Stanford University School of Medicine.

Drs. Raymond L. Hintz, Ronald Rosenfeld, Daryl M. Wilson and Ann Bennett are conducting the three-week trial in 10 adult, normal volunteers to meet the U.S. Food and Drug Administration's first requirement in any clinical test—that the drug be shown to be safe.

If no complications are detected in this trial, the FDA is expected to okay tests at Stanford and 11 other medical centers in the U.S. to determine whether children with insufficient growth hormone of their own will grow when injected with the laboratory-produced hormone.

The trial with children could begin within a month of the completion of the adult test, according to Hintz.

Of the 10 volunteers in the adult study, five will receive daily injections for a week of natural growth hormone, while the other five will be injected with Genentech's engineered growth hormone. After a one-week rest, the two groups of volunteers will exchange treatments.

Volunteers will receive physical exams, including tests to check the functioning of their hearts and livers, as well as tests to see if the engineered hormone can produce metabolic effects identical to those that result from natural growth hormone.

-more-

Although adults can't grow anymore because their long bones have become totally calcified, they do respond to growth hormone with changes in the blood levels of glucose, insulin, and of the hormone somatomedin, a substance which mediates some of the many actions of growth hormone, according to the researchers.

If FDA approval is granted, the tests in at least 20 children deficient in growth hormone will last a year. This will be the first treatment of growth hormone, natural or manufactured, for these children.

In California, the centers involved in this facet of the study will be Stanford, the University of California at San Francisco, and the University of California at Los Angeles.

Abroad, studies have already been approved by the United Kindgom Department of Health for a clinical trial at the Great Ormond Street Hospital of Sick Children in London. A year-long test of Genentech's growth hormone will begin in February. Ten of the children will be receiving their first treatment of any type of hormone. The other 10 have already been receiving growth hormone extracted from human cadaver pituitaries.

If the trials proceed as scheduled, what can be expected? The scientists are cautious in making premature claims. But this much is known from past experience in treating children with natural growth hormone.

Growth hormone will not make every short person tall. At the present state of knowledge, there is no hormone which is going to make someone bigger than his own genes dictate.

Patients must be carefully selected. A child who comes to the clinic must be determined to be free from other disease. Only after ruling out disease and heredity, treatment with growth hormone can begin.

Growth usually follows after treatment, but not everyone responds. Some children begin to grow after the dosage is increased, while about 10 percent develop antibodies and no longer react to treatment.

Treatment must begin early. A child is more receptive to the hormone at a young age. The chances of response begin to diminish after age 10.

There are some complications. Once a child has started growth hormone therapy, two psychological problems may be encountered, according to the pediatricians. First is the so-called King Kong complex in which the child who has always been small begins to grow and becomes very aggressive.

The second involves the child's inability to change his body image—he sees himself as a small, sweet child. When he becomes the same size as his friends, he loses his uniqueness.

Parents most often suffer from inflated expectations and hope the first injection of the hormone will make their child normal size. Although there is an initial growth spurt, it usually takes months to approach normal, and it can take years if therapy is started late.

While treatment results with the manufactured growth hormone will not be known for some time, researchers are already thinking of other clinical applications. At a recvnt FDA symposium these were suggested: Treatment of short stature accompanying Turner's syndrome, a disorder of sexual development affecting 1 in 2,500 females born in the United States; treatment of the arthritic and short stature effects of juvenile rheumatoid arthritis; enhanced healing of wounds, cartilage damage and fractures; and treatment of burns, stress ulcers, and osteoporosis.

And this is only the beginning.

FOR INFORMATION CONTACT: Bobbi Navickis (415) 497-6911

Notes to editors: Following is background material for heart-lung transplant.

The 1972 discovery of the drug cyclosporin A set the stage for this new attempt to successfully replace at the same time both heart and lungs. Cyclosporin A circumvents two previously formidable obstacles in heart-lung transplants: the slow and imperfect healing of the windpipe and life-threatening infections.

Dr. Bruce A. Reitz, assistant professor of cardiovascular surgery at Stanford Medical School and head of the transplant team, estimates that the Stanford team may do three to four of these operations each year, considerably fewer than the 20 heart transplants it did last year. Not only do fewer people need a combined heart-lung transplant, but suitable donors are also harder to find, Reitz says.

As is true with heart transplant candidates, only persons judged to be dying and unable to be helped by any less drastic treatment will be considered for the operation.

For some patients with heart disease, replacing only the heart is not good enough. Their lungs have been irreparably damaged due to the high blood pressure resulting from a poorly-pumping heart. Patients with damaged lungs, resulting from either a failing heart or widespread disease in the lungs themselves, are a poor risk for a heart transplant. The damaged lungs resist the "new" heart's efforts to pump blood into them, straining the heart. The only recourse is to replace both the heart and the lungs.

Likewise, some patients who initially have just lung disease, such as pulmonary hypertension, or pulmonary or cystic fibrosis, end up with a damaged heart that needs to be replaced as well.

Although the success rate for heart transplants has improved in recent years (70 percent of the transplant patients now survive the first year), the replacement of lungs has met with failure. According to Reitz, in the 38 attempts up to 1977, only two patients lived longer than three months after surgery, and none survived longer than ten months.

The three previous combined heart-lung transplants, performed between 1968 and 1971, fared even worse: the patients survived only 14 hours, and 8 and 23 days.

One of the reasons success is yet to come in transplanting lungs is that the windpipe, or trachael tube, fails to heal completely, resulting in infection, air leakage or bleeding. The windpipe is slow and difficult to mend for a number of reasons, a major one being its scanty blood supply, which hinders healing.

Corticosteroids, until now the standard drugs given to prevent the body from rejecting the "foreign" lungs and an essential ingredient in the high success rate of heart transplants in recent years, slow down and antagonize the healing process even more. Cyclosporin A is such a find because it enables the surgeons to replace or decrease the dose of coricosteroids, and doesn't itself interfere with the windpipe's healing.

Cyclosporin A, a metabolite of the fungus Trichoderma polysporum, is composed of 11 amino acids hooked together to form a ring. It was discovered by Sandoz Pharmaceuticals of Basel, Switzerland. Sandoz has made the drug available for clinical trials to transplant surgeons in Britain, France, Canada and the United States during the last three years, and it has been used in kidney, liver, pancreas and heart transplants.

Exactly how cyclosporin A works is unknown, but it appears to inhibit the action of those cells of the body's defense system responsible for rejecting foreign tissue, the so-called T cells.

Reitz and Drs. Nelson A. Burton and John L. Pennock lay the groundwork for the operation working with monkeys. In tests during the past several years, they reinvestigated the possibility of heart-lung transplants with their new drug in hand. Results were encouraging. Three of seven monkeys receiving "new" hearts and lungs and being treated with cyclosporin A survived more than 140 days after surgery. Two are still living, 14 and 15 months after the operation.

-more-

Reitz says a major problem will be finding suitable donors. Donors will have to have both normal heart and lungs, and must be compatible with the blood type of the recipient.

Reitz anticipates that some donor lungs will be disqualified because they are infected.

Infection is the bugbear of transplant patients. The drug therapy, which suppresses the body's immune system, thus preventing rejection of the transplanted organ, also permits infections to gain a toehold. Infection has caused a third of all deaths in heart transplant patients, and the most common site has been the cells of the lungs. Another critical advantage of cyclosporin A is that it doesn't interfere with the immune system responsible for battling bacteria, while it inhibits those responsible for rejecting transplanted organs.

The choice of donors will be limited to those near Stanford Medical Center, because a method hasn't been worked out by which a heart and lung combination can be transported for any distance outside the donor's body, Reitz says. Since 1977 the number of potential donors for heart transplants has been greatly increased by a method to protect the heart in sterile bags and place it on ice after removing it from the donor and flushing it with a cold salt solution. Cooled hearts have been flown to Stanford in a chartered jet from up to 450 miles away.

Although, conceptually, replacing both the heart and the lungs (essentially the entire contents of the thoracic cavity) seems a mighty job, its actual execution is elegant, involving relatively few cuts and reconnections, once the overlying membranes are cut away.

Four surgeons work an average of four hours. Tubes are inserted into a major artery and two major veins just before they enter the heart so that the patient can be put on a heart-lung machine that will keep the blood flowing to all the other parts of the body. After the blood has been successfully detoured through the heart-lung machine with the help of clamps downstream on the artery and vein, the heart and lungs are removed with only three cuts; the ascending aorta (the major artery), right upper chamber of the heart and the windpipe, or trachae, are severed. The new heart and lungs are then put in, the three areas reconnected, and the blood diverted back through the new heart.

If the operation seems relatively simple, the balancing act performed after the operation does not. The body's immune system must be suppressed enough that it cannot mount an offensive against the new thoracic tenants, but yet not so suppressed that it cannot fight off the least infection.

The new organs must be monitored regularly to see if they are under seige, and if they are, the dose of immunosuppressive drugs increased to avert a rejection.

A technique was developed several years ago to sample directly a small piece of the heart for early signs of rejection that can't be detected by more conventional methods. A thin, flexible wire with a clipper at the end is inserted in the patient's jugular vein and threaded down into the transplanted heart to obtain a small sample of tissue. This ability to directly assess the heart transplant accounts for a goodly part of the increased success rate in recent years.

This technique has not proved useful for lung transplants, Reitz says, and so it is hard to detect the first signs of rejection when only lungs are transplanted. In the combined heart and lung transplants, evidence of rejection of the heart means also rejection of the lungs, and therapy can be begun before the situation is out of control.

Although cyclosporin A is the best drug yet found for heart-lung transplants, it is not without its undesirable side effects. Most serious is the potential development of malignant lymphoma, a form of cancer that has been previously associated with immunosuppression. Three kidney transplant patients in recent clinical trials of cyclosporin A conducted at Cambridge University in England developed lymphomas in the first year. The research team in England has since lowered its dosage of cyclosporin and no new lymphomas have been detected.

Other side effects of the drug include mild cases of hair growth on the face and limbs, tremors, and toxicity to the kidney.

Cyclosporin A is still an experimental drug on which all the evidence is not in. Yet no drug now available to a transplant patient, who must take drugs the rest of his life, are without undesirable side effects. Cyclosporin A may give a patient with failing heart and lungs, who otherwise faces a sure and near death, the possibility of a successful transplant, Reitz says.

City Desks: This is the last of two articles concerning the biotechnology industry and its growing relationships to academe.

FOR IMMEDIATE RELEASE

STANFORD—

Five years ago genetic engineering research faced an uncertain future because some people feared it would create microbial monsters that might escape the laboratories and decimate the population.

The genetic engineering problem today is no longer some unimaginable disease threatening to kill people off.

The problem now is its commercial success, and the accompanying stresses and strains it has imposed on the universities that gave birth to the new technology.

"The vascillations and soul-searchings at Harvard and Stanford have had wide press coverage in recent months," observes Arthur Kornberg, a Nobel Prize winning biochemist and one of the patriarchs of the DNA field.

"But there is no putting this genie in the bottle. For years we promised applications of genetic chemistry and immunobiology. Now when they are within reach we must not circumscribe them or blunt them.

"What each of us does face and must grapple with is how to shape our scientific lives and cope with the sudden and increasing public awareness and concern with what we do."

The relationships of Stanford University biomedical scientists to the biotechnology companies now emerging in the San Francisco Bay Area are a topic of study by a committee appointed recently by Vice President for Medical Affairs and Dean of the School of Medicine Lawrence G. Crowley.

Headed by Eric M. Shooter, chairman of the Department of Neurobiology, the committee has been directed to examine these relationships in the light of the University's consulting policy, and to determine their potential impact on the School's academic programs.

Consulting has been encouraged at Stanford and other institutions not only because it results in a two-way transfer of knowledge between scientists and industry, but it is also an indirect form of subsidy to the university, particularly since many professors' market value on the outside is often greater than what academe can afford to pay them.

Under this policy, a professor may consult up to 52 days per year, which most agree is generous. The consulting policy recognizes that when faculty members hold officerships and consultantships with private firms there may be conflicts of interest.

Stanford has not found it necessary to develop rules of conduct regarding conflicts of interest, except for government-sponsored research which mentions that potential or actual conflicts of interest should be disclosed. An example would be when a professor undertakes a government-sponsored project while working on similar research with a private firm.

Disclosure, however, of such matters is now voluntary and some believe it may not be adequate under the pressures in which some faculty working with industry may find themselves.

"I rather doubt," says Crowley, "that with the profit motive so strong and the stakes so high that we can leave everything up to the individual—that everyone in the School will have the character and wisdom needed to preserve academic standards and to combat pressures.

-more-

"If we don't have wise policies, the motivation for a considerable amount of research in academia could be shifted significantly away from the search for new discoveries towards applications and commercial success.

"And this movement could sweep our graduate students and postdoctoral fellows as well."

Henry S. Kaplan, an astute and tough-minded professor of radiology who pioneered new cancer treatments, thinks the root problem is that some professors are given equity in the new biotechnology companies.

"This is a new ingredient in the picture," Kaplan says, "and it's not trivial.

"There might be subtle pressures on such faculty members with respect to secrecy in their research which under normal circumstances would have been treated as open.

"We may have situations in which faculty within the same or different departments ceased to communicate effectively with each other because now their proprietary interests relate to different companies.

"One could imagine perhaps graduate students or post-doctoral fellows who do research for professors with company connections, finding themselves under pressure to do work of direct benefit to the professor's company."

Kaplan says the normal consulting arrangements sanctioned by the University had some tradition about them.

"They were not very much abused," he says. "The new situations now offer the possibility for abuses that could be quite serious."

Not everyone, however, is in agreement with Kaplan's view.

Hugh McDevitt, a professor of medical microbiology and medicine, asks, "What's so different about a chemist who consults for Monsanto and gets paid a yearly consulting fee? Does this bend his loyalties any more than the guy who gets paid in stock?"

Kaplan's counter argument is that company stock may involve large amounts of money.

"If this money is going to the individual rather than his research program" Kaplan says, "it will certainly change the scientist's public image.

"Professors would be viewed as businessmen."

Kaplan adds the alternative of royalty income turned over to the research fund under the University's patent policy would be viewed differently.

"The public wouldn't object to industry's paying royalties to universities for faculty inventions if the income was used to support research and education."

Stanley N. Cohen, professor and chairman of the Department of Genetics, as well as other faculty members interviewed for this report view the conflict issue less alarmingly.

"I agree," says Cohen, "that the university has the obligation to set guidelines on these matters, and it has. But the real issue is whether or not affiliations of faculty with industry influence academic missions and directions.

"This will have to depend on the basic outlook of the faculty member, his integrity, feelings about academic values, his reason for being at the university.

"In theory these outside influences can happen subtly. There is no way they can be fully monitored. This is true not only when we consult for industry but also for the government.

"The important thing is disclosure. We must be fully open about our relationships and be very careful keeping the lines clean between our university activities and outside consulting."

Thomas C. Merigan, professor of medicine, feels that faculty members should not make industry commitments that might compromise their fields. -more-

"I've got to be able to speak out accurately and freely," he says. "I must relate to my students unhindered by consulting connections, and pick research projects in areas that seem challenging and important.

"We mustn't get hooked on consulting in a way that we lose sight of our mission, which is to teach and advance knowledge."

Another scientist who asked not be identified raises a different point. He says he finds it interesting that similar questions have not been raised about profits made by faculty from writing textbooks, which can yield hundreds of thousands of dollars to the author.

"Faculty members do much of their book-writing on University time, often using its facilities," the scientist observes. "Their Stanford affiliation is used in promoting their books, and they may require or recommend use of their books by the students they teach.

"Moreover, their books often lead to substantial fees from medical-legal, and industrial consultations."

The scientist adds, "The potential for true conflict of interest in this area seems much greater than in the case of limited consultations outside the University.

"Yet, few eyebrows are raised about the outside income to the textbook writer, even when the profits come from work that does not involve significant scholarship."

Kaplan thinks the University should be entitled to a portion of such outside income.

"I would like to see a policy evolve that would cover all outside income across the board—book royalties, honoraria, consulting fees," he suggests.

"The percentage contributed to the University need not be so large as to stiffle this type of initiative."

Noting that the School of Medicine already has such a policy—"a percentage of the faculty's clinical earnings is returned to the School"—Kaplan adds, "It would be fair treatment to apply it across the board."

If issues of money, secrecy and potential conflicts, are hotly debated, another concern is also surfacing.

"We have to worry," says Nobel Laureate Paul Berg, "about the distortions that the development of molecular biology in the private sector may inject into the traditional systems of scientific inquiry."

Although Berg welcomes industry's interest—"I think it is a plus"—however, he points out that many of the new companies are now competing for the talents of bright young scientists with the universities.

"The attractions offered by industry are formidable," he says. "The universities cannot compete on financial and even on other grounds.

"It raises a concern in my mind that we may lose a better part of a generation of molecular biologists, cell biologists, and geneticists who will not work at universities. Who will then achieve the breakthroughs of tomorrow?"

Some of these issues will undoubtedly be examined by the Shooter committee when it begins to meet in the coming weeks. But there is one other area which will have to be addressed by the University as a whole. This is the issue of whether Stanford should take an equity position with respect to products of faculty research.

Stanford University President Donald Kennedy has not ruled out the possibility of the University and its professors participating in commercial ventures, but for the moment he has put such a consideration in abeyance "because of the potential conflicts of interest it might generate."

"The University, I think, has an entirely legitimate interest in returning some reasonable portion of this new value that it is creating to nourish its academic needs," he says.

"But the University has to be reasonable in its demands and has to keep certain principles in mind.

-more-

4-4-4 "It should be fair and equitable with the faculty, and it should desire to increase the rate of diffusion of potentially valuable new technology into human services.

"The University cannot in its own strategies, whatever these may be, put the return of value ahead of the obligation to act in the public interest."

Given these limits, Kennedy adds, and assuming the University can stay clear of conflicts of interest, it should pursue opportunities to return value.

"At the moment I am inclined to believe that the mechanism that is keeping us off the slippery slopes is our patent licensing policy," he says.

But patents on faculty inventions have problems too. They trouble Berg who thinks patents distort research.

"How much can the logical outcome of a research project be influenced," he asks, "if there is a chance of obtaining a patentable result versus one which may be scientifically important but with no market value?"

The problem applies equally to faculty and students.

"If there is a chance to make money," Berg says, "and the University encourages work that is patentable, the research emphasis will undoubtedly bend in that direction."

Another dimension of the patent question is secrecy, according to Berg. "People may not be so willing to discuss germs of ideas if they're potentially patentable. The overall result will be to reduce scientific exchange. Certainly it won't increase it.

He favors creating a national foundation to deal with all university patents.

"Conflict would be eliminated," he argues. "Some of the royalties would flow back to the universities to support research and other needs and some would be used to support research training nationwide," he says. "It would be a logical thing."

In the current debate it is easier to affirm the growing pains of the new biotechnology than to prescribe for them. Neither academe or industry, which must depend heavily on academic science, have any precedent or models to follow. As Kornberg puts it, "Unlike the postwar electronics revolution which originated mostly in industry, the earliest industrial applications of genetic engineering and immunobiology came exclusively from academic laboratories."

Moreover, the growing industry-university interactions are complicated by the fact few businessmen understand academe and few of the biomedical scientists understand the business world. Recently, for example, a businessman on a local television show complained how hard it was to manage professors.

He said, "They will discover something in the lab that will raise six new questions while the company is interested in just one thing."

The businessman added, "It's hard sometimes to keep them in line."

Kornberg, who referred to such pressures earlier, said he hopes the scientists who have been and will remain the major source of these commercial efforts will have the character and wisdom to resist them. He believes companies can be successful fostering and working in an academic environment. "In so doing," he says, "they will attract the best scientists and thereby have the most important ingredient for success."

It should be stressed the interactions between industry and academe did not begin with genetic engineering and immunobiology. They have existed at Stanford for many years, developing gradually but on a similar if not larger scale.

Business, chemistry, engineering, physics, earth sciences and so on have had long-standing ties with the private sector. This two-part examination of such links found no faculty members who feel these links have harmed the academic enterprise. In fact, in most cases they have greatly enhanced it.

Editors: This is the first of two articles on industry-academia relationships and the business of science funding.

STANFORD—

Quietly, yet steadily in the past few months, an enclave of small biotechnology companies has been settling on the Midpeninsula near Stanford University. They are in the race to exploit commercially two fields that barely existed five years ago, genetic engineering and hybridomas.

Even though the University is not involved in these ventures, the firms are settling here because they depend on molecular and cell biologists, geneticists, immunologists, and computer scientists to work for them as employees or consultants.

Stanford and its School of Medicine have the talent the companies want. The basic genetic engineering or DNA cloning technique was developed by scientists at Stanford and the University of California in San Francisco. The two institutions hold the patents for the process. Stanford scientists also have contributed key refinements in hybridoma technology and related instrumentation, bringing its application closer to reality.

DNA cloning is a technique that permits the tailoring and transplantation of genes from one species to another. The technique permits the introduction of genes into easy-to-grow bacterial cells, enabling construction of "bacterial factories" that can synthesize a variety of biologically produced substances. The process, using spliced or recombinant DNA, has been called the ultimate technology, and its benefits are now emerging in medicine, with the testing of gene spliced insulin, human growth hormone, and interferons.

Hybridoma technology, invented in England at about the same time as recombinant DNA, makes possible artificially created cells that produce pure or "monoclonal" antibodies. Such highly specialized antibodies,instead of the usual mixture produced by the body's immune system, not only provides a powerful tool for research but can be expected to provide quicker detection of viruses, bacteria, and cancer cells. The long-range promise of monoclonal antibodies is that they might prove useful in therapy, or as vaccine replacements.

The prospect of big payoffs from research originated by academic scientists has attracted active commercial interest. The university scientists too are aware of the growing importance of these technologies to the world economy. In principle, they note, bacteria could be engineered to produce almost anything created naturally by plant and animal cells. This could have a significant impact on a host of industries, from energy and chemicals to agriculture.

"This drives many companies to get in the act right now to develop the research capability and the people needed to make these applications possible," says Stanford Nobel Laureate Paul Berg.

"Understandably," adds his colleague, Nobel Laureate Arthur Kornberg, "the scientists who provided the ideas, techniques, and practitioners of genetic chemistry are reluctant to be excluded from its financial rewards by enterpreneurs and venture capitalists."

Deserving though the scientists may be, their new role in business ventures raises real concerns. Among them are whether they should share information with their colleagues, how much money they deserve for their discoveries, how the university should share in their gains, and how to resolve possible conflicts between teaching, research, and consulting activities.

-more-

2-2-2 Last week the Stanford Committee on Research held its first open hearing on the matter. This week Dr. Lawrence G. Crowley, vice president for medical affairs and medical school dean, appointed a committee headed by neuroscientist Eric Shooter to examine faculty outside activities in light of the University's consulting policy.

In a memo, Crowley noted that outside opportunities for some scientists have become exceptionally attractive and the rewards relatively great.

"These conditions," Crowley added, "have created unusual pressures and problems, including potential conflicts of interest for our faculty and the potential for distortion of our educational activities.

"The full consequences are difficult to foresee, but we should attempt to evaluate them carefully."

Stanford University President Donald Kennedy, a biologist himself, also sent a letter urging faculty to use "caution and deliberation" in responding to the flurry of overtures from genetic engineering firms.

In an interview, Kennedy said he is concerned about three issues: the public credibility of the scientific enterprise, the health of basic research, and the preservation of the university as an environment in which first quality research and related teaching can go on.

"I think the very new environment in which we find ourselves offers opportunities, but also real problems in all three of these areas," he said.

Kennedy said he fears an increasing proportion of the research efforts of "our best scientists may come to take place in off campus environments where they will be less accessible to students and colleagues who choose not to work for industry."

"And this," Kennedy stated, "will result in a diffusion away from the kind of intellectual center the university represents."

Kennedy also sees real problems of openness and scientific exchange. The evidence is unmistakable, he thinks, that the informal exchange between individuals and the general feeling of collegiality are rapidly disappearing.

"We all recognize cases in which scientists were competitive and close-mouthed with one another," he said, "but to add the problems caused by good old venal human nature to those created by a powerful profit motive is to invite the exacerbation of the situation."

Kennedy's final point is the credibility of science.

"I see evidence from talking to all kinds of people outside the University that the escalation of value undergone by some of the gene-splicing venture companies, and the large paper profits made by some scientists, are inviting suspicion," he said.

"When a professor says in an interview that his discovery will possibly lead to a cure for a disease, people will ask, 'I wonder what company he is tied up with?' "

And that Kennedy finds troublesome, particularly if some of the new business ventures associated with the names of prominent university scientists fail.

"I worry," he said, "that people are going to remember the claims—maybe even have the company's prospectus on file—and wonder if the scientists who seemed to offer so much in the way of hope were in fact participants in a kind of deception."

Pointing to recent critical newspaper articles on the gene-splicing industry, Kennedy added, "Suspicions are already beginning to grow."

Like Kennedy, Kornberg welcomes industry's interest in genetic chemistry applications, but he deplores the business practices of some companies. He urges his colleagues to "have the character and wisdom to preserve academic standards and combat pressures for secrecy and gimmickry."

"There are dangers," Kornberg says, "if genetic engineering companies appropriate a generation of senior scientists as consultants and junior scientists as employees and seal them off from free exchange of new knowledge."

-more-

But there are motivations beyond just sharing in potentially lucrative ventures that lure academic scientists to industry. One is a genuine desire on the part of the scientists to see their work applied for the public benefit.

"If in fact we do believe there are practical benefits from molecular biology," says Berg, "then we should all applaud that there is a private industry eager and willing to move in the field of application.

"After all these years of doing this research, and insisting on how important it is and what it would mean to mankind, it is somewhat hypocritical to be negative when the possibilities to apply this information are presented."

Another reason why some scientists now look for closer industry ties is survival. Universities, having to compete in a market dominated by wage and salary rates, face a difficult, if not uncertain economic future. Traditional sources of support are falling off or not keeping up with inflation. And President Reagan's policies are expected to limit severely the funds available for higher education and research.

These problems drive many academic scientists to look in the private industry sector for support.

"I am in a stage of my research when there is an obvious practical application," says Hugh McDevitt, an eminent Stanford immunogeneticist. "Presently the federal government is unable to respond with new funds to support these new developments.

"Industry, on the other hand, is prepared to do so and more rapidly than the government through its normal funding mechanisms."

McDevitt also stresses that academic scientists throughout the country are forming similar alliances with industry to advance genetic engineering and hybridoma research.

"We have to do the same in order to remain at the forefront of our fields," he says.

Leonard Herzenberg, a genetics professor adds another reason. "Producing monoclonal antibodies on a mass scale is beyond the capabilities of individual scientists and university laboratories. Private industry can do this effectively and has performed an excellent service to the research community."

Interferon expert Thomas C. Merigan says that before gene-spliced interferon was produced, there was not enough of it to go around so that it could be tested.

"We are now in a position, without of course knowing what the result will be, to carry out the definitive interferon tests," he says.

The connection between industry and faculty at Stanford is not new or without precedent. It was a Stanford engineering professor, Frederick E. Terman, who three decades ago persuaded Stanford to open an industrial park, leasing the land to businesses.

This development sealed the marriage of academic science and commerce in Palo Alto. The age of electronics had arrived, and high-technology companies saw the advantage of being next door to an acclaimed university that welcomed them by sharing personnnel and ideas. The San Francisco Peninsula became the most fertile area in the world for the development of electronics and acquired the name "Silicon Valley."

They say if Terman provided the spark for Silicon Valley, then the Stanford genetic chemistry pioneers will be the key to the "Recombinant DNA Valley," the cluster of companies now sprinting into the biotechnology age. With this will come new jobs for young scientists and technicians, a more efficient technology transfer of the fruits of university research, and needed funding for the University.

Consider, for example, the new companies or subsidiaries launched in the Palo Alto area recently:

- **Cetus Immune Corporation (CIC).** A subsidiary of the Berkeley-based recombinant DNA firm, CIC, with Stanford professor Hugh McDevitt, will place its emphasis on human hybridoma monoclonal antibody technology, the firm explains. "The long-term diagnostic opportunities will also be addressed."

McDevitt, its principal scientist, has been joined by several other Stanford faculty members—Edgar G. Engleman, F. Carl Grumet, Thomas C. Merigan, and William S. Robinson, all members of the Cetus 28-member Scientific Advisory Board.

• **Cetus Palo Alto Corporation (CPA)** is the firm's second subsidiary with Stanley N. Cohen, a Stanford geneticist and clinical pharmacologist, as the principal advisor. Work at CPA involves the development of new methods for making antibiotics, research in brain chemicals called neuropeptides, and novel diagnostic tests for viral, bacterial, and protozoic infections.

Cohen, who co-invented the molecular cloning techniques with the University of California's Hebert Boyer, founder of Genentech, has been joined by three other Stanford professors on the Cetus Scientific Advisory Board—Stanley Falkow, William S. Robinson, and Jack Remington. Genetics research associate Annie C.Y. Chang, is also associated with the subsidiary.

• **Becton Dickinson Corporation** is an established company based in New Jersey. Its Mountain View laboratory is expanding its activities to exploit potential applications of monoclonal antibodies to medicine. A new facility for that purpose is under construction at the firm's Mountain View site. A major supplier of health care products—syringes, needles and a variety of diagnostics, Becton Dickinson has successfully produced and marketed worldwide the fluorescence activated cell sorter.

Developed in 1971 by scientists in the genetics department, this space-age tool, which separates cells on the basis of their fluorescent label, is an important adjunct to the emerging monoclonal antibody technology.

Leonard Herzenberg, professor of genetics who pioneered the biological applications of this device, has consulted for the firm for the past 10 years.

• **IntelliGenetics,** a new firm was founded by three Stanford faculty members to provide computer software to the molecular genetics industry, and to provide consultations regarding computer applications.

The three scientists are Douglas Brutlag and Lawrence Kedes in the School of Medicine, and Edward Feigenbaum in Computer Science. Another computer scientist, Peter Friedland, is also associated with the group. The four have been at work for more than four years researching applications of artificial intelligence to molecular genetics.

The DNA cloning industry, experts believe, will need sophisticated computers to control many of the delicate processes of bacterial growth fluctuations and other variables involved in gene-splicing applications, and to monitor each stage independently. If nothing else, a professor commented, IntelliGenetics should make a fascinating marriage between the two supertechnologies of tomorrow.

• **DNAX Ltd., and DNAX Research Institute of Molecular and Cellular Biology** are the latest addition to the enclave of biotechnology companies being established in Palo Alto., The brainchild of Alejandro Zaffaroni, a successful biochemist-businessman and president of ALZA Corporation, DNAX and its research institute have been formed to "exploit three advanced technologies—genetic engineering, immunobiology, and drug delivery systems—to make new products," the firm states.

Products will include high potency, specialized antibodies for diagnosis and treatment of disease and for use in industrial processes.

In addition, DNAX will direct efforts in developing organisms for large-scale production of pure, high potency biological macromolecules to be used as hormones, vaccines, interferons, growth factors and diagnostic reagents.

The ALZA drug delivery technology will be used to target the delivery of these agents to specific sites and to regulate their administration so as to minimize toxic effects.

The DNAX six-member scientific advisory board includes Stanford's Charles Yanofsky and Nobel Laureates Paul Berg and Arthur Kornberg. Three others serve on the firm's immunology panel, Roger Kornberg, Samuel Strober, and Irving L. Weissman.

Kornberg says he is enthusiastic about DNAX because of the commitment of its corporate managers to provide an academic atmosphere, and to promote exchange of information through prompt publication, open seminars, and fellowships.

more

Another aspect Kornberg likes is the company's commitment to return, if successful, a substantial amount of money to support research in academic institutions. "I believe such a commitment is unique among genetic engineering companies," he says.

Kornberg, like other Stanford colleagues, is concerned that the role of scientific advisors in DNAX be presented accurately and not subjected to rumor or speculation. He adds, "The work we do in our academic laboratories will not be done with any special advantage to DNAX."

In the past 30 years many forms of academia-industry interaction have evolved at Stanford. One of these is the Industrial Affiliates Program. It is an attempt to provide a link between faculty and company scientists and engineers, and to provide a way for companies to learn about university research in progress.

Affiliates programs involved more than 18 departments from Aeronautics to Thermosciences. Companies pay fees for participation in the educational seminars and other activities, and often these lead to consulting ties.

In Biochemistry alone the program brings more than $150,000 a year for use in academic activities. This arrangement seems to have worked well without the potential conflicts that have been feared in some ventures.

A more intensive Affiliates program is the recent consulting arrangement between the Syntex Corporation in Palo Alto and the Department of Medicine.

Under the agreement, Syntex has made a substantial gift to an Institute of Biological Investigation formed by the department's 80-member faculty. While Syntex is given no access to Stanford technology the agreement requires institute members to consult for Syntex as needed for up to eight days a year. If at the end of the consultation, Syntex wishes to develop a long-term relationship on a project, it can do so by a separate contract arrangement.

Such projects, however, must have the approval of the institute's scientific board and must meet the same rigorous standards as grant proposals to the federal government.

The gift monies to the institute will be used to support young faculty which the deparmtent needs.

"Most consulting," comments Kenneth Melmon, chairman of the Department of Medicine, "is now done on an ad hoc basis benefitting only the faculty member and is of little value to academe and often to the companies when it involves complex questions.

"The consultation is often shallow. The company requesting help on a complex problem does not always get the best advice, and the consultant almost never gets any feedback. Bad consulting leads to poor relationships.

"What we have done with Syntex is a relationship that builds on academic values. We have a desire to provide responsible advice and to use it as a basis for a long-term productive relationship.

"If we give Syntex and others some answers, we are likely to solidify industry support. In the past we could not get such support on other than a charitable basis."

Although this report has concentrated on the School of Medicine and the evolving relationships of its faculty and the biotechnology industry, it would not be complete if it did not touch upon the role of the Office of Technology Licensing (OTL).

Patent licensing remains an important source of funding for university research and for supporting the ever-increasing costs of education at Stanford. Since its inception in 1970, the OTL has negotiated nearly 74 agreements for development and marketing inventions for the faculty—many of them emanating from the Medical School. Total license royalties since that time have exceeded $2.7 million, and last year's royalties reached $655,000.

What of the future? It is clear, as one scientist puts it, "that the development of genetic engineering in this area is an inevitable as Hewlett-Packard." But because this industry was developed entirely by academic scientists, and because of the scale of their involvement in the field of application, it has raised many agonizing questions and led to a serious re-examination of all industry ties with the university and its faculty.

"The fact these issues are being debated openly and in an uninhibited way," the same scientist adds, "is an optimistic sign of the health and vigor of the academic enterprise.

Everybody wants to make the links between academic research and industry as open and cooperative as possible, and with all the safeguards needed for a vigorous and independent science."

STANFORD—

An ad hoc committee to review outside consulting activities of the full-time faculty of the Stanford University School of Medicine has been appointed by Dr. Lawrence G. Crowley, vice president for medical affairs and dean.

Headed by Dr. Eric M. Shooter, chairman and professor of the Department of Neurobiology, the committee will examine faculty outside activities in light of the University's consulting policy.

If conflicts exist, the idea is to recommend changes or additional guidelines.

Crowley said scientific advances emanating from research in genetic engineering and hybridomas have opened opportunities for scientists responsible for these developments to participate as consultants or in other roles.

Noting private industry's interest in the commercial possibilities of these developments, Crowley added, "These conditions have created unusual pressures and problems, i cluding potential conflicts of interest for our faculty and potential for distortion of our educational activities.

"The full consequences are difficult to foresee," Crowley said, "but we should attempt to evaluate them carefully."

Crowley said such evaluations are in progress in many universities around the country.

"The president, provost and all the vice presidents are concerned about this issue at Stanford," he said. And the Research Committee of the University had been asked to review the matter."

In addition to Shooter, committee members include Paul Berg, biochemistry; Hugh McDevitt, medical microbiology; Stanley N. Cohen, genetics; Kenneth Melmon, medicine; John Collins, surgery; William Northway, Jr., radiology; and John L. Wilson, associate dean for faculty affairs.

In addition, Carl Hitchner, managing attorney for medical affairs, and David Mendelow, associate dean for administration in the School of Medicine, will serve as resource persons.

TWO STORIES

STANFORD—

Dr. Ora M. Rosen will present the eighth annual Windsor C. Cutting Lecture Thursday April 9 at Stanford University School of Medicine.

The lecture, open to the public, commences at 4:15 in the Medical School's Fairchild Auditorium.

Rosen, chairman of the Department of Molecular Pharmacology at the Albert Einstein College of Medicine, Yeshiva University, will deliver a talk entitled "Mechanisms of Hormone Action during Differentiation of a Cultured Adipocyte Cell Line."

Educated at Barnard College and at Columbia University College of Physicians and Surgeons (M.D., 1960), Rosen's background is in molecular biology, endocrinology and pharmacology. In addition to being chairman of her department, she is also director of scientific affairs of the Diabetes Research and Training Center of Albert Einstein College.

Rosen's main research interest concerns the molecular events involved in hormone action. Recently she isolated an enzyme influenced by the hormones insulin and epinephrine and important in regulating activity of other proteins involved in heart and muscle cell metabolism.

Rosen's research has added to knowledge of how cells regulate energy production in health and disease, and her work in diabetes and other metabolic diseases may lead to selection of better chemical agents for therapy of these diseases.

The Windsor Cutting Lectureship was established in 1973 by the faculty of the Department of Pharmacology, in memory of Dr. Cutting, former professor and chairman of the department. Dr. Cutting, who died in 1972, also served as dean of the Medical School from 1953 through 1957 and as dean of the University of Hawaii Medical School from 1963 through 1971.

STANFORD—

Dr. Tag E. Mansour, the Donald E. Baxter Professor of Pharmacology at Stanford University School of Medicine, has been awarded a Macy Faculty Scholarship for 1981-82 from the Josiah Macy, Jr. Foundation of New York.

The award provides support for Mansour to spend six months pursuing scholarly research at three institutions in England and Egypt beginning in October.

Mansour, who is chairman of the Pharmacology Department at Stanford University School of Medicine, plans to pursue new strategies in the development of drugs to curb parasitic helminth (worm) infections. Current drug therapies against the various helminth diseases, which are a significant health problem throughout most of the developing and undeveloped areas of the world, are inadequate because they harm the human host as they eradicate the worms, explains Mansour.

The advances of biology and medicine in the Western world have been only frugally applied to this area of research, Mansour laments, since the diseases are not a major problem in Western countries. Nevertheless, the need for such research, in terms of human suffering, is undeniable: an estimated 180 million people have the infection schistosomiasis, caused by the blood fluke *Schistosoma*; 650 million are infected with *Ascaris*; 450 million afflicted with *Ancylostoma*; 250 million with *Filaria*; and 20 million with *Onchocerca*, Mansour reports.

One promising avenue of research Mansour has followed for several years involves searching for biochemical and molecular characteristics in worms unique and distinct from those in their hosts. Finding such unique traits gives researchers specific targets for drug therapy, he explains.

By way of example Mansour cites the parasitic worm's mobility which is crucial to its survival in the host intestinal or circulatory system. "The chemical serotonin seems to play a role in the control of movement," he says. "If we can block the serotonin action selectively, we would have a successful chemotherapeutic agent," he suggests.

As a Macy scholar, Mansour will spend five months in England at the London School of Hygiene and Tropical Medicine where he will deliver the Heath Clarke Lectures in November, and at the National Institute for Medical Research at Mill Hill. He will also spend a month at the Naval Research Institute in Cairo, Egypt.

A member of the Stanford faculty since 1961, Mansour is a native of Egypt. He received his bachelors degree from the University of Cairo and his Ph.D. in pharmacology from Birmingham University Medical School in England.

He serves on several national and international health advisory committees and is the author or co-author of nearly 100 scientific publications.

The Macy Faculty Scholar Award Program was established in 1972 to encourage medical and public health school faculty members to study in a "fresh environment." Mansour is one of 26 recipients this year, selected from 144 applicants nationwide. During the Program's eight years, the Foundation has supported 231 faculty members from 70 institutions in the United States and Canada to the tune of $4.7 million. There have been nine Stanford University faculty recipients.

The Josiah Macy, Jr. Foundation was created by an endowment from Mrs. Kate Macy Ladd in 1930 for the advancement of medicine in the United States.

STANFORD—

A scientist at Stanford University Medical Center who has made some startling discoveries about the energy-generating structures in cells is also acquiring new information about certain rare genetic diseases.

Dr. Douglas Wallace, assistant professor of genetics at Stanford, has been probing the genes of the small cellular energy-producing organelles called mitochondria. These particles have long fascinated biologists. Thought to have evolved within cells from bacteria-like invaders eons in the past, they intrigue scientists concerned with symbiotic (mutually beneficial) relationships. They also intrigue geneticists because, in mammalian cells, they comprise the only sites outside the cell nucleus to harbor self-replicating DNA. The notion that as many as several hundred of the "semi-autonomous" mitochondria may reside inside each cell has led at least one biologist, Lewis Thomas, to wryly question who is actually running the show.

Underscoring more soberly the significance of the mitochondrial presence in mammalian cells, Wallace is now uncovering evidence that mitochondria and mitochondrial DNA may play an important role in certain genetic diseases in man.

Wallace and his colleagues, Dr. R. Giles, Dr. H. Blanc, Dr. H. Cann and J. Case, recently reported a key finding. While studying the inheritance pattern of human mitochondrial DNA, they found that the mitochondrial DNA follows a maternal lineage. It is the mother's set of mitochondrial genes that is passed to her children, never the father's. "This maternal inheritance pattern is unique," explains Wallace, and unlike all other genes, which may come from both mother and father. "It was a most surprising and intriguing observation," he reports.

The researchers discovered maternal inheritance by examining mitochondrial DNA from blood platelets and skin of individuals from several families. Using "restriction enzymes," (proteins that cut the circles of mitochondrial DNA at specific points determined by the sequence of nucleotides), they found that the pattern of mitochondrial DNA fragments from the children was always the same as their mother's and never like their fathers'.

This observation, together with the knowledge that there are a number of genetic diseases that follow a maternal inheritance pattern and that affect those body tissues with high energy demand (the nerves and muscles), led Wallace to wonder whether mitochondrial DNA can undergo changes, or mutations, that cause disease.

-more-

Leber's hereditary optic atrophy is one of the better known of the maternally inherited diseases. Other possible candidates for mitochondrial DNA coded diseases are certain of the mitochondrial muscle disorders, which are characterized by mitochondrial alterations in some muscle tissue cells. Mitochondria in these cells often have an abnormal shape and physiology.

"Our goal is to determine if these diseases are in fact due to mutations in the mitochondrial DNA. Then we will be a lot closer to understanding their biological basis," states Wallace. "Knowledge of the maternal inheritance pattern of such diseases would be invaluable in counseling the families," he adds.

Leber's syndrome is a fairly rare condition, but nevertheless it is among the more common inherited diseases, Wallace observes. Usually, it's first noticed in adolescence as a "hole" in the vision caused by atrophy of the optic nerve, and it may wax and wane, often ending in blindness.

In the numerous human pedigrees from families whose members have Leber's atrophy, it has been observed that the syndrome is consistently inherited through the mother, never the father. In order to investigate the possibility that Leber's optic atrophy may be controlled by a gene on mitochondrial DNA, Wallace is currently seeking Leber's atrophy patients to participate in some clinical tests.

Wallace plans to take blood samples from the volunteers in order to search for unusual patterns in the mitochondrial DNA and to examine their inheritance. He also hopes to study the patients' cells for evidence of mitochondrial abnormalities. "We hope these studies will confirm that Leber's syndrome is due to a defect in mitochondrial DNA," he says.

But showing convincingly that a mitochondrial-related disease is caused by mitochondrial DNA changes is no simple task. It's complicated by the fact that the small circular molecules of mitochondrial DNA do not contain enough information to code for more than approximately 20 polypeptide chains (the structural components of proteins). Mitochondria are made from hundreds of proteins. This means that nuclear DNA also plays a major role in orchestrating mitochondrial protein formation.

Pedigrees from some families with mitochondrial muscle disorders follow the maternal inheritance pattern expected if a mitochondrial DNA gene coded for the defect. Other pedigrees of mitochondrial muscle disorders show the standard "Mendelian" pattern of inheritance, and these would presumably reflect a defective mitochondrial polypeptide controlled by nuclear DNA, Wallace notes.

But the mitochondrial muscle disorders are rarer than Leber's disease and the pedigrees are few and far between. This makes the maternal inheritance pattern observed much less certain, cautions Wallace. "We need to examine many more pedigrees to state with any authority whether or not certain types of muscle disease are maternally inherited, and therefore candidates for mitochondrial DNA coded diseases," he says.

One further test of the nuclear or mitochondrial origin of an inherited characteristic involves a special technique Wallace devised for human cells in culture. He removes the nucleus and its enclosed DNA from the cell he suspects of having a mitochondrial DNA coded alteration. This leaves behind the cell's cytoplasm where the only remaining genetic material is mitochondrial DNA. The "enucleated" cell is then fused with a normal cell—the result Wallace calls a "cybrid."

-more-

If the cybrid expresses the mitochondrial alteration of the original enucleated cell, it provides proof that the mutation was carried on DNA from the cytoplasm, Wallace explains. Eventually, with this method, he and his colleagues hope to confirm the mitochondrial origin of these diseases and learn more about the proteins controlled by genes in mitochondrial DNA.

Although the questions about mitochondrial DNA coded diseases are compelling, equally intriguing are some of the basic biological puzzles, Wallace admits. How and why mitochondrial DNA is maternally inherited are still matters for speculation, he comments. Perhaps the huge egg cell, with its many mitochondria merely overwhelms the small sperm's contribution, he suggests. Or the sperm's mitochondria may just be destroyed. The fact that maternal inheritance of mitochondrial DNA is found in many other plants and animals hints at an evolutionary advantage to the scheme, Wallace says.

"This is how basic biology fuses with clinical medicine," Wallace adds. "Most of our effort must go toward understanding the human mitochondrion as a biological phenomenon before the clinical answers will come."

Wallace's work is supported by the National Institutes of Health, the March of Dimes Birth Defects Foundation and the National Science Foundation.

STANFORD—

Coronary artery bypass surgery is now so safe that death or sickness resulting from the operation is infrequent enough to be considered nearly a random event, according to D. Craig Miller, a cardiovascular surgeon at Stanford Medical Center.

Speaking at the American College of Cardiology's recent San Francisco meeting, he said that the surgery, with its attendant medical care, has become so refined that it's almost impossible to identify someone for whom the surgery is a high risk.

In fact, he adds, the operation is becoming safer and safer, despite the fact that the patients are becoming, in general, sicker and older.

Miller's calculation of the safety of the operation is based on his analysis of nearly 2000 Stanford heart-surgery patients. He compared 1000 patients who were operated on between 1971 and 1975 with 973 operated on between 1977 and 1979 in Stanford's department of cardiovascular surgery. He did the study with Drs. Norman E. Shumway, Edward B. Stinson, and Philip E. Oyer.

They found that the chance of suffering a heart attack within a short time after the operation fell from 8.7 percent in the earlier group to 4.6 percent in the latter; the chance of dying was only half as great, declined from 2.4 percent to 1.2 percent. By 1979, the chance of dying was down to 0.68 percent.

Miller's conclusions are at odds with the consensus reached last December by a conference held at the National Heart, Lung, and Blood Institute. It concluded that the risk of death from the surgery was between 1 and 4 percent in the best of circumstances, and between 10 and 15 percent in the worst, that being when a patient has congestive heart failure and his heart is not pumping blood efficiently.

The conference's estimates, based on large randomized and non-randomized studies done throughout the 70s at a number of institutions, are probably not valid in 1901, Miller says. The risk of dying from the operation has been reduced during the decade and is really ow much lower; at Stanford in 1979, it was only two-thirds of one percent, he says.

True, he says, the risk, to some extent, is related to in which hospital the surgery is done. (A recent study found that the death rates for bypass surgery in 15 of the most prestigious cardiac surgery hospitals in the United States ranged from 0.3 to 6.4 percent.) But, that Stanford has such an enviable record shows the know-how is now had to make the operation safer at other hospitals also, he says.

Controversy is not new to coronary artery bypass surgery. Since it became common approximately 12 years ago, the operation has had to withstand the skepticism that it was worth neither the risk nor the money, that perhaps medication, in many cases, could do as well. It has survived to become one of the most popular surgeries--in the United States last year, 110,000 operations were performed at an average cost of $15,000 each.

The most common reason the operation is done is to alleviate angina pectoris, or chest pains, at can't be controlled with medication. The pains result from some parts of the heart not receiving enough blood because the arteries feeding the heart, the coronary arteries, have become partially or totally blocked.

-more-

2-2-2

In the operation surgeons replace those of the four coronary arteries that have become clogged. They usually graft veins taken from the upper leg in place of the blocked arteries, enabling blood to flow freely through the heart again.

The more recent group in Miller's study included older patients and more females, who are at higher risk than males. (Eighty-three percent of those in the study were male, a reflection of the much greater incidence in heart disease in males than females.) Also, compared with the patients in the first half of the 70s, more of these later patients had high blood pressure, diabetes, elevated blood lipid levels, congestive heart failure, diseased arteries leading to brain, and severe chest pains called unstable angina.

They also had, on average, a greater number of heart arteries diseased, 3.3, compared with 2.7 in the earlier group, and required, on average, a greater number of grafts (2.95, up from 2.4.) and had suffered more heart muscle damage due to previous heart attacks.

However, even though, in general, sicker and older, and therefore seemingly at a greater risk, the latter group fared much better.

Miller attributes the improvement to a number of causes. With experience have come better expertise on the part of the anesthesiologists, the surgeons, and the nurses, who care for the patients before and after the operation. He says more precise ways to diagnose the patient's problems before the operation have been developed, and drugs that can better stabilize the heart before and after the operation have been identified. Also, there are better ways to protect the heart from damage during the operation.

In fact, the operation has become so refined that in the 1977-1979 group, the only identifiable factor that increased the risk of a patient's dying was an emergency operation on an unstable heart. However, in the 1971-1975 group of patients, anyone who had required an emergency operation, had a diseased left main artery, had high blood pressure, or had congestive heart failure, faced a greater chance of dying.

In the 1977-1979 group, only females and a few of those patients who required coronary endarterectomy (a procedure used to unclog those arteries which are totally blocked) could be tagged as likely to have a heart attack either during or within a short time after the operation. In the earlier group, age, an acute heart attack before the operation, disease in the left main heart artery, and the method used to protect the heart from damage during the surgery surfaced as risk factors.

Miller says that because many of Stanford's patients are referred to Stanford from elsewhere, one thing for which he could not completely test may increase the risks. He could only determine how well the left ventricle, the heart's main pumping chamber, was working in 32 percent of the patients. This factor has proven to be a risk in earlier studies done elsewhere, implying that severe muscle damage from many previous heart attacks put a patient at greater risk.

The decision as to whether or not an operation is worth the risk should be based on what's true now, Miller concludes, not what was true in the earlier phases of the development of coronary artery bypass surgery.

STANFORD—

A Tuesday noon lecture series on "Women and Health," sponsored by Stanford Medical School's division of family medicine, will begin March 31. All lectures, open to the public without charge, will take place in room M106 in the School of Medicine.

The presentations, many of which may include films, exercises, or other types of audience participation, will include:

- **March 31—Women as Mothers**—with Julie Olsen Edwards, a National Endowment for the Humanities Scholar and author of *Motherhood in the 80's*
- **April 7—Menstruation: Theory and Practice**—with Emily Culpepper, a feminist freethinker
- **April 14—Health and Obesity: Risk or Riddles**—with Stacey Fitzsimmons, chronic disease epidemiologist
- **April 21—Prescriptions for Women**—with Judy Martin, M.D., from Stanford's division of family medicine
- **April 28—Minority Women and Health**—with Esperanza Walters, R.N., M.P.H., director of the South Bay Area Health Education Council
- **May 5—The face in the Mirror is Mine**—with Ginny Connell, a marriage and family counselor; co-founder and administrator of "The Alive Place" in Sherman Oaks
- **May 12—Women and Work: A 24-hour Job**—with Julie Olsen Edwards, co-director of the Cabrillo College department of early childhood and family life education
- **May 19—Movement for Health**—with Jean Couch, M.S., co-author of *The Runner's World Yoga Book* and a yoga instructor on KQED television
- **May 26—Networking**—with Jeanne Flyntz DeJoseph, C.N.M., Ph.D., assistant director of nursing services at Stanford Hospital; and with Marita Grudzen, health care consultant.

The division of family medicine is part of the department of family, community and preventive medicine at Stanford. The noon lecture series may be taken for academic credit by medical students. For more information, call 497-7874.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

A workshop for women—though men are invited too—entitled "Designing your Medical Career," will be offered on Saturday, April 4, by the Katharine McCormick Society, the Stanford Medical Students' Association, and the American Medical Women's Association Professional Resources Research Center.

The conference, to be held at CERAS, Stanford University, from 8 to 5, will provide an opportunity for women in medicine to think about and discuss their career plans. It is open to interested medical students, graduate students, postdoctoral scholars, housestaff and others. The major focus will be on academic medicine, with discussion of the steps necessary to make it a feasible career option.

Speakers will include such prominent members of the medical community as Lawrence Crowley, M.D., Sarah Donaldson, M.D., and Frances Conley, M.D. Medical student Laura Esserman will introduce the program.

Topics will include historical perspectives on women in medicine; academic medicine versus private practice; alternative work strategies such as split residencies and job-sharing; how to promote institutional acceptance of part-time academic positions; handling positions of power and responsibility; handling stress and femininity in the workplace; resume building and organizing time; and options for Ph.D.'s.

One purpose of the meeting is to help organize Stanford women into a cohesive and active group, and to recruit women to organize the next workshop—tentatively planned for next fall.

The cost of the workshop is $5.00, including lunch. Advance registration is required, and the deadline is March 25.

For further information, contact Dr. Joan Kendig, Department of Anesthesia, at (415) 497-6455.

STANFORD—

Pianomime, a Stanford based non-professional mime troupe, will offer a benefit performance of "Bagatelles" on March 29, at 3, in Stanford University's Little Theater.

Proceeds from the event will go to the Pediatrics Department of the Medical Center.

Directed by Stella Bensadon, a Bay Area teacher, director and performer of mime, "Bagatelles" originated as a workshop for her mime students. It is a full-length performance of mime comedy and drama, using piano accompaniment.

Besides Bensadon, members of the troupe are: David Gollub (pianist), Barbara Milligan, Larry Russick, Gigi Weix and Kazuko Yamamoto.

Bensadon's international background in mime includes studies in Israel with Yoram Boker, and in Paris with Etienne Decroux, the teacher of Marcel Marceau. She has also studied with Ella Jaroszewics, star of the Tomashevsky Mime Theater.

In 1974 Bensadon led a Stanford troupe called "The Company."

Tickets of the upcoming performance may be purchased at the door. The price will be $3.00 for adults, and $2.00 for children.

STANFORD—

As recently as two or three years ago, Peggy Richardson's presence in an intensive care unit startled many of the nursing staff.

"They would say to me, what are you doing here," she recalls. "The patient isn't eating!"

That attitude—that the critically ill patient is beyond help nutritionally—is changing, however, says Richardson, as more efficient methods of feeding these patients have been devised and the need has become more clearly established.

Richardson, a registered dietician at Stanford University Hospital, credits a 1974 article in *Nutrition Today* with exposing the severity of the problem. In that article, entitled, "The Skeleton in the Hospital Closet," the author argued that patients, especially the critically ill, were often neglected nutritionally because a typical intravenous feeding was too low in caloric value to do any good. As a result, many patients were suffering from malnutrition, although they were not diagnosed as such.

"This was really the beginning of a change in attitude within dietetics and the field of medicine," says Richardson. "More emphasis was put on nutrition after this article came out. . .especially the nutritional status of critical care patients."

According to Richardson, as recognition of the need grew, so did the ability to meet it. Specifically, something called total parenteral nutrition (TPN) was developed in the mid-seventies.

In TPN, higher doses of dextrose and amino acids can be given to a patient through the use of the body's major veins, the jugular and the superior vena cava. Previously, intravenous feedings were carried out in peripheral veins, which could not tolerate the higher caloric density needed to provide sufficient nutrition.

At the same time, the development of a fat-solution in Europe, which could be given simultaneously, says Richardson, enabled patients to receive total nutrition—protein, fats and carbohydrates—for the first time.

"TPN really opened up a whole new ballgame," says Richardson. "Patients could be adequately nourished who might otherwise suffer from malnutrition."

At Stanford, Richardson spends roughly half of her time working with these potentially malnourished patients in the medical surgical and cardiovascular ICUs; the other half of her work day she spends with cardiovascular patients who have undergone fairly routine procedures and need nutritional counseling rather than therapy.

The prevailing philosophy among dieticians, says Richardson, is "if the gut works, use it." The nasal-gastric route is preferable, she says, because studies have shown nutrients received by the patient in this manner are better utilized in the body than through intravenous feedings.

IV feedings are also enormously expensive. As Richardson observes, "TPN is an expensive way to get your steak and potatos."

Typically, the cost of one IV bottle, which provides roughly half of the average 2500 calories needed per day, is $70. Richardson estimates that at any given time there are between 15 and 20 patients in the Hospital who are on TPN.

After sustaining a major injury, whether from trauma or from the bodily stress of surgery, says Richardson, a patient's nutritional needs jump dramatically. Enormous amounts of calories are expended in order to heal the body tisues, rebuild muscles and regain normal respiratory functions.

Since nutrition is not the first focus of interest following a severe injury, says Richardson, a patient may already be suffering from a calorie deficit by the time his or her condition stabilizes.

-more-

2-2-2 "In a truly critical case," she says, "we begin immediately with TPN, but the general rule is if a patient is unable to consume food orally one week to 10 days after injury,they should be put on parenteral nutrition."

Although complete nutritional assessments are not done as frequently as Richardson would like, they are done on a limited basis, with a physician's order. The purpose is to provide a baseline for measuring a patient's progress.

One of the best and most immediate indicators for determining protein breakdown, says Richardson, is a nitrogen balance test, which can be done quickly by measuring the urea nitrogen excreted, with the amount of protein being taken in.

"Ideally," says Richardson, "we want a critical care patient to be anabolic which means taking in more nitrogen than excreted and building tissue."

In a nutritional assessment sheet, which Richardson devised, other ways of determining a patient's nutritional status include measuring skin folds of subcutaneous fat to determine energy stores, and establishing a patient's immunity status.

All the while, the underlying question during treatment remains, "Is this doing the patient any good?"

We are constantly assessing whether the patient is improving," says Richardson. "If nothing is happening, then we can change the composition of the IV solution."

Usually when patients are on TPN, eliciting cooperation from them is a moot point, since they are too sick to care. But once TPN is stopped and the patient is started on nasal-gastric feeding, cooperation becomes essential.

Individual tolerance levels are also taken into account. One of Richarson's patients, who was badly injured in a car accident, is currently receiving nasal-gastrically 5000 calories a day.

"There is no way a little old lady could tolerate this level," says Richardson, "but younger people don't have the metabolic problems an older person might have."

"The high dextrose levels of TPN will ultimately create delayed gastric emptying, and while it (TPN) doesn't affect the appetite per se, a patient feels full on smaller amounts of food.

"When you start on nasal feeding, sometimes you get stomach distention and the patient simply doesn't feel like eating or they don't like the foods that are best for them."

Allergies and glucose intolerance can also complicate a patient's ability to begin eating normally again. So soft foods and liquid substitutes are often used as oral feedings are gradually increased.

Although there are frustrating times when a patient's recalcitrance prevents recovery, says Richardson, there are compensating moments of success as well.

"It's very gratifying when you do succeed," she says.

For the past three years, Richardson has served on Stanford's Total Parenteral Nutrition Committee, which is headed by Robert Sladen, assistant professor of anesthesia. The committee acts as an advisory group, reviewing TPN procedures currently in use and developing protocols for the Hospital's program

Represented on the committee are physicians, surgeons, pharmacists, nurses and dieticians.

And just recently, according to Richardson, a nurse who specializes in TPN was hired by the Hospital to coordinate the activities of the committee.

"This is a major step forward," says Richardson, who eventually hopes to see patients assessed nutritionally before, as well as after, surgery.

"Studies have been done," she says, "that have shown patients who go into surgery malnourished, are apt to do less well than those who are properly nourished. Ideally, it would be nice to be able to assess these patients in the future. For one thing, it would be more cost-effective because their recovery would be faster and they would get out of the Hospital that much sooner."

Richardson, who came to Stanford in 1972, received her B.S. degree from Cornell University in 1965. Her experience also includes a one-year internship at St. Mary's Hospital in Rochester, Minn. and work in a research unit at Yale University Hospital in New Haven, Conn.

Her interest in the field of nutrition apparently came about naturally.

"There's a very simple reason," she confides with a laugh, " I love food."

STANFORD—

Stanley Falkow, chairman of the Department of Medical Microbiology at Stanford University Medical Center, and Dr. Susumu Mitsuhashi of Japan have been awarded the Paul Ehrlich-Ludwig Darmstaedter Prize, the highest German honor for scientific work in the field of medicine.

They received their award in the Church of Paul in Frankfurt on March 14, the birthday of Paul Ehrlich, a Nobel laureate of 1908 and pioneer in immunology and bacteriology. They will share the 80,000 German marks (approximately $40,000) prize money.

Both scientists have investigated why medicines that kill bacteria can suddenly become ineffective. They discovered that small, circular DNA molecules, called plasmids, found in the bacteria, are responsible.

Mishuhashi found that these plasmids contain genes that code for resistance to antibiotics, and that these plasmids can be passed between bacteria, with a resultant rapid spread of antibiotic resistance among the bacteria.

Falkow showed that the plasmid exchange takes place not only between related bacteria, but between unrelated bacteria as well. He found that a pathogenic bacterium that antibiotics can kill suddenly becomes resistant to the antibiotics when the bacterium acquires from a harmless bacterium a plasmid carrying an antibiotic-resistance gene.

The bacterium that causes meningitis in children is usually killed by penicillin. But in the last few years, it has become resistant to the antibiotic. Falkow found that this resistance could be traced to the meningitis-causing bacterium's acquiring a plasmid from a harmless bacterium normally found in the intestine. Since the human intestine has a resident population of bacteria, Falkow's finding says that we are always in danger of carrying around this source of drug resistance with us.

Falkow received his Ph.D. degree from Brown University in 1961. After serving as assistant chief of the Department of Bacterial Immunology at Walter Reed Army Institute of Research for three years, he joined the Department of Microbiology at Georgetown University Medical School in Washington, D.C. in 1966. In 1972, he became a professor in the Department of Microbiology and Immunology of the University of Washington Medical School in Seattle, where he has remained until he came to Stanford this year.

Falkow has written more than 100 scientific articles and chapters, has written the single most complete text on plasmids and is on the editorial boards of *Infection and Immunity* and *The Journal of Infectious Diseases.*

STANFORD—

X-ray pictures in the future may uncover the 30 percent of lung tumors now missed, tell if the coronary arteries in the heart are clogging up, and detect lipid build-up in the carotid artery that could lead to a stroke. They may also be able to replace some exploratory surgeries and diagnostic catherizations.

Medical researchers at Stanford and elsewhere are developing ways to select what will be in an X-ray picture, and the pictures are beginning to tell more by containing less. The researchers are capitalizing on principles of physics, are utilizing advanced electronic equipment, and are fashioning sophisticated computer programs to subtract out the incidental anatomy. They're being rewarded with a sharp picture of the structure under scrutiny.

In a standard X-ray picture, a lung tumor lurking behind a rib gets missed, a gall bladder, tucked under a lobe of the liver and obscured by bowel gas, carries its load of stones uncaught. The problem is that the conventional X-ray picture is cluttered with too much of the anatomy, and what's really of interest sometimes gets eclipsed.

So out go the old films, which can't be selective enough in what they record, and in come the microcomputers, video displays and tricks of physics. The result is pictures of bodiless bones, stark blood vessels and revealed gall bladders.

Drs. William Brody, director of Stanford's Advanced Imaging Techniques Laboratory, and Albert Macovski, professor of electrical engineering and of radiology, are developing such an X-ray machine.

This machine, built by General Electric, is like no other existing at present. It employs "dual energy imaging," or less concisely said, two beams of X-rays, one of high and one of low energy, to form the image.

This new method is more sensitive than the old. It allows doctors to gather the same amount of information using a lower dose of X-rays or concentration of iodine, or both, than the old conventional film does. (Iodine is used as a label to locate the structure of interest.) For a comparable dose of X-rays or iodine, the dual energy imaging method tells more than the standard method.

Macovski says this work could bring great improvement in the diagnosis of two types of diseases: those at present that can't be reliably diagnosed with X-rays, such as bone and lung tumors, and those that can only be detected with very invasive techniques, such as exploratory surgery or the insertion of catheters into blood vessels.

Symptomatic patients and surgery candidates will not be the only ones to benefit, he says. The system could be used to screen persons without symptoms, but at high risk, yet not enough risk to try a risky diagnostic procedure. It could also be used to follow a patient's progress after surgery.

Brody is striving to refine the technique to where the coronary arteries will be able to be visualized, something which is impossible today and which obviously would be a quantum leap in the detection of heart disease.

Dual energy imaging exploits a phenomenon of physics: When X-ray beams pass through a material, they lose some of their energy to that material. Just how much energy is lost and in what form depends upon the nature of the material; it is different for the iodine tag and for the body's soft tissues and for its bones.

-more-

As the patient, lying on a table, is slowly transported through the dual-energy imaging machine, razor-thin X-ray pictures are taken of the part of the body being examined. The information from each slice is fed into a computer automatically, where the difference between how the high and the low energy beams have fared is rapidly calculated. The differences between the change in each beam is used to create the final picture.

As the beams pass through the body's soft tissues, the loss of energy by either beam is slight, so the shadows from all the soft tissue regions are nearly cancelled in the computer image. In the iodine-tagged tissue, however, because of the nature of iodine, one beam loses much more energy than the other, and the difference calculated by the computer is large.

The computer can go through all these calculations quite rapidly and within three to four seconds piece together the information from the various slices to form a sharp picture of the iodine-tagged tissue.

Dr. Brody has been using the machine on patients with vascular problems for over a year on an experimental basis. Patients with chest lesions are also now being scanned, he says.

An alternative method being developed by several researchers around the country to improve the quality of X-ray pictures is digital fluoroscopy.

Brody and Macovski are acquiring such a machine soon.

The digital refers to the use of computers to analyze the data emerging from the fluoroscope. In the procedure, a "before" picture of an area of patient is taken. Then a chemical, which has been engineered to lodge in the structure of interest, is given to the patient, followed by an "after" picture. The computer is instructed to find the difference between the two pictures, which should be only the administered chemical, outlining the desired structure.

One problem with fluoroscopy, Macovski says, is that if the patient moves, the picture is garbled, a difficulty not encountered with the dual-energy imaging method.

It is also less flexible than the dual-energy imaging machine, he says, but it should be cheaper.

Digital fluoroscopy will be useful for diagnosing, among other things, whether the carotid arteries have built up lipid plaques, which could possibly break loose and cause strokes. This is because the chemical can quickly reach the right area once it has been injected into a vein, and so the patient's moving is ot a great problem.

Digital fluoroscopy is nearing commercial availability, Brody says. But the dual-energy imaging machine is still a few years down the road, he says.

STANFORD—

Stanford President Donald Kennedy announced at a medical staff meeting Tuesday evening that the main problems that have divided community and faculty physicians at Stanford Univerasity Hospital have been solved.

"Not every single issue has been resolved, some are inherently 'rolling'," he said. "But the issues that can be resolved have been."

A formal report and recommendations of the Palo Alto Community Physicians and Stanford Medical School Liason Committee, which worked for more than two years to resolve the conflicts, will probably be made to the Hospital Board of Directors at its April 15 meeting, he said.

Differences between community and faculty physicians reached a crisis point on Aug. 1,1978, when the Hospital Board of Directors issued a memorandum saying that community physicians' access to some specialized hospital-based services should be limited in the future. That policy, while not changing the admitting privileges of community physicians, would have restricted future community specialists from certain laboratory privileges.

Individual affiliation agreements have now been submitted by the Hospital for several community physicians whose access to particular services has of special concern to community physician groups, Kennedy said.

Also, criteria for appointment, reappointment and promotion of the voluntary clinical faculty has been drafted and agreed upon, he reported. A formal appeal mechanism of negative decisions on reappointments and promotions, and a review of departmental decisions on initial appointments by a dean will also be instituted for the volunteer clinical faculty, he said.

In addition, a special class, clinical associates, has been created for any qualified voluntary clinical physician for whom there is no space in the appropriate department or service at the time of his appointment.

These voluntary clinical faculty guidelines were drafted by a committee consisting of equal numbers of fulltime and clinical voluntary faculty members, led by Dr. John Wilson.

The main liason committee, with Drs. Walter Arons and Lawrence G. Crowley as co-chairman, has in addition developed application and appeal procedures and criteria for the replacement of existing community physicians in the Hospital services and laboratories, Kennedy said.

Problems not completely solved in the present report will have to be considered by the liason committee and the Hospital Board at intervals, Kennedy said. Reviews of the access arrangements for existing or new Hospital services or laboratories will need to be carried out a regular basis by the Hospital Board, he said.

STANFORD—

One hospital offers its nurses a free trip to Hawaii after a year on the job. Another offers a $1000 reward. In still another, nurses receive 40 hours' pay for working a 24-hour weekend.

These "gimmicks"—as Duane Walker, R.N., M.S., Stanford's director of Nursing Services, calls them—reflect the extreme competition in nurse recruitment that's taken place among hospitals, nationwide, over the last few years.

Out of 1.4 million nurses in the U.S. today, says Walker, only about 700,000 are working, leaving at least 100,000 nursing vacancies throughout the country.

Stanford, too—with 48 current full-time vacancies—is involved in the massive effort to recruit and, more importantly says Walker, retain nurses.

But it's a costly venture. Dan Heath, assistant director of Finance for the Medical Center, explains that the development of special programs over recent years has led to increased expenditures.

For the year 1980-81, according to Heath, costs over and above intended spending for orientation and recruitment amount to about $800,000.

It does, however, seem to be paying off. While the average rate of nurse turnover nationwide is currently 68 percent, at Stanford it's now only 25 percent, says Walker, compared to 35 percent when he arrived here three years ago.

And, he otes, Stanford's one-year retention rate for the 106 new nursing graduates hired this past year is 90 percent. This contrasts dramatically with the national one-year dropout rate of 85 percent for new grads.

An example of Stanford's innovative approach is the offer of a new 12-hour shift for the medical intensive care units (I.C.U.'s). Nurses will work 7 A.M. to 7 P.M.—or vice versa—for just three days a week. Implemented this month, the system's results will be carefully evaluated in the near future.

Upon announcement of the system, says Walker, 26 vacant positions were filled within two weeks. And there is already a waiting list to work on the unit, preference being given to current staff nurses.

Stanford now has three full-time nurse recruiters, led by coordinator Katie Bray. One project they're involved with is a series of "job faires," designed to sell the Hospital to potential nurse recruits.

There are two types of faires, says Walker, both advertised through the media. One is a department's open house, for which displays are presented and tours conducted. So far, these have been held for the operating rooms, critical care I.C.U.'s, medical nursing and pediatrics nursing units.

The other type is long-distant, held in various cities across the country. Private companies sponsor the faires in large hotels, and up to 200 hospitals pay for use of individual booths. Stanford sends staff nurses and clinical nursing coordinators—as well as recruiters—to run booths at these events.

-more-

"Happy nurses are the best recruiters," says Walker. That's why the Hospital has devised a special incentive for its staff: all non-exempt Hospital employees who successfully recruit nurses receive a cash bonus. The award is $250 after six months' retention, and another $250 after twelve.

And increasing incentives for nurses themselves to choose Stanford is naturally a priority concern.

Nurses' salaries—also hiked up in the present market, where demand exceeds supply—are competitive here with other hospitals in the area, says Walker, adding that the Bay Area offers some of the highest salaries in the country.

The housing shortage in this area of the state can be fearsome, says Walker. For this reason, Stanford now provides temporary housing for newly-arrived nurses, allowing them at least three months to find their own homes.

Refresher courses are offered to nurses returning after several years away from work, those who require up-dated information on medications and procedures.

And for new graduates—not hired by Stanford until recently—a special orientation program has been designed. Each graduate couples up with an experienced nurse, receiving an evaluation from her at the end of two months.

Nurses have a tough job, says Walker, often working nights, weekends and holidays. Yet their personal lives are very important to them, he contends. Most enjoy recreation, while many are concerned with children at home.

Eighty percent of Stanford's nurses work fewer than 40 hours a week. Flexible working hours are negotiated individually for those with outside commitments, says Walker.

Of nurses who leave the Hospital due to stress or "burn-out," he notes, many later join private companies—where they may be paid more.

In fact, one reason for the national nursing shortage, says Walker, is that increasing numbers of women—the main source of nurses, traditionally—are now seeking careers in numerous other fields, open to them today as never before.

Nursing administrators at Stanford have conducted two job satisfaction surveys in the last three years, says Walker, to take the pulse of nurses' feelings about their work.

Through questionnaires, they were asked what pleased them most at Stanford, what didn't please them, and what was important to them on the job.

Results were shared with the staff, who were then asked for further recommendations. These were of two categories, explains Walker: those which could take place at the nursing unit level, and those which would require his (administrative) involvement.

It was discovered through one of the surveys, says Walker, that communication was not all it could be between the nursing administration and staff.

To rectify this and build morale, a nursing services newsletter was started, along with weekly announcement sheets and monthly staff meetings. For Valentine's Day, 1981, a special "thank you" flyer was distributed to nurses, with warm comments from both the administrative btaff and several patients themselves.

-more-

Also, a distinguished lecture series for nursing was set up by the Department of Nursing Services. Barbara Nichols, president of the American Nurses Association, was the series' first speaker, on February 25.

For the year 1980-81, says Heath, the original budget for ursing recruitment at the Medical Center was $220,000, plus orientation costs. But additional expenses were incurred for most of the innovations mentioned above.

In fact, says Heath, $460,000 is being spent, in all, for nurse recruitment. Orientation costs, he says, are $330,000 over what was expected. And additional compensation costs amount to $215,000.

Who foots the bill? The patients do, says Heath, as costs are passed along, with an ever-rising price tag on hospital care.

Future possibilities for nurse recruitment and retention, according to Walker, include expanding the Office of Nursing Research—which now has a staff of three, led by Dr. Lois Welches—into a regional center for nursing research. Funding is being sought through a grant from the federal government.

The center would focus on identifying and solving problems of nursing practice. Already, an educational program including workshops and seminars is underway, with the purpose of teaching nurses basic research skills. A survey designed to determine how many nurses would attend such classes, says Walker, demonstrated an overwhelmingly positive response.

Also under consideration is the feasibility of developing an on-site day care service for Medical Center employees. Carol Ann Bergman of Personnel has been coordinating a task force to explore this issue, with representatives from Nursing as well as other departments.

Another plan, says Walker, is to set up a satellite baccalaureate nursing program in conjunction with San Jose State University, at no cost to Stanford. (Stanford disspelled its own nurses training program several years ago, due to competition over funds in the Medical School.)

And U.C. San Francisco, says Walker, may develop a satellite master's program here. Tuition costs to nurses, he points out, would be much lower under these programs than if Stanford were to reinstate its own.

Plans are also underway for a cardiovascular institute to open in January, 1982. This would entail a six-month training program in cardiovascular nursing for all interested nurses—some of whom might be attracted to work at Stanford, hopes Walker. The costs of the institute have not yet been determined, he explains, but tuition fees would necessarily be charged.

"The Medical Center as a whole is known for teaching, research and patient care," says Walker. "And nurses should be involved in these different areas too, not just the latter."

"Professional excellence by excellent professionals" is the motto supporting Stanford's national reputation as a center of excellence for nursing practice, says Walker.

"We hope nurses will be attracted here by that, rather than by the idea of being near to San Francisco or the Golden Gate Bridge," he notes.

Friends of Nursing is a new community group forming to meet with Walker in an advisory capacity. Its purpose will be to solicit financial support for nursing activities and to increase public awareness.

In order to better market the Hospital—locally and nationally—as a desirable place to work, the group will help keep a close watch on both the images and realities of nursing at Stanford.

STANFORD—

Pictures at an Exhibition, by the composer Moussorgsky, is a challenge to the best pianists of the world, says Luther Cobb, M.D.

"I certainly never thought *I* could play it," says Cobb, a surgery resident in the lab of assistant professor Ronald Merrell. But he did—at his first recital since high school, given recently at Stanford.

As an undergraduate at Michigan State, explains Cobb, he started working on the piece under the guidance of a graduate student in the Music Department.

"I even auditioned in the Department for a duo major, with chemistry. But they decided my commitment was not strong enough, and they were right." In order to excel as a musician, he explains, one's commitment must be total.

But Cobb continued anyway on his own, keeping a piano in his dorm room until he graduated in 1974.

As a first-year medical student at Stanford, Cobb had no piano. He finally bought a piano but missed a teacher's guidance.

"If you're just playing for yourself, fooling around, you don't do as well," he explains.

While an intern in surgery here, Cobb resumed piano lessons. His instructor ever since has been Adolph Baller, a professor in Stanford's Music Department. According to Cobb, it was largely Baller's encouragement that led to his recent recital.

"Polishing a piece for performance is the best growth hormone for a musician," says Cobb, in the true words of a physician musician.

When he's not playing music, Cobb is concerned with research for improving treatment of diabetes and other diseases of the pancreas. Working with dogs as subjects, he and his colleagues are attempting to isolate islets (small glands) from the pancreas. They hope to be able to transplant the islets, instead of the whole pancreas. Pancreas transplantation itself, notes Cobb, is still in the experimental stages.

Born in Arkansas, Cobb discovered a love for the piano when he was five or six years old. He was one of six brothers, all of whom learned to play on an old piano given them by an aunt.

"My older brother was taking lessons from a piano teacher who lived next door. He would practice, and then I would take a seat and play his lesson."

Essentially, Cobb taught himself to read music and play, even before starting lessons. He grew up performing in several neighborhood recitals a year, organized by his teacher.

Today, Cobb participates in a musical group of physicians led by Rodney Anderson, M.D., a urologist at the Santa Clara Valley Medical Center. "There are lots of musical people around here," says Cobb, whose favorite composer is Chopin.

Preferring classical music in general, he nevertheless enjoys such moderns as Gerschwin and Scott Joplin. As for jazz, Cobb likes to listen. "It's a totally different skill to play it," he says.

There was a good turnout for his recent recital, says Cobb, especially from the Medical Center community. He hopes, since the initial try was a success, to perform more in the future.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

The fifth annual George A. Zimmermann lecture will be given at Stanford University Medical Center on March 19, by W. Ian McDonald, Ph.D., F.R.C.P.

McDonald, who is professor of clinical neurology at the Institute of Neurology, Queen Square, London, will discuss "Three problems of Multiple Sclerosis," at 5, in room M-106. The lecture is free and open to the public.

McDonald is an honorary consultant physician to the National Hospitals, Queen Square and Maida Vale, and to the Moorfields Eye Hospital of London.

Established by the Department of Neurology in 1977, this annual lectureship is part of a gift from the late George A. Zimmermann, a longtime San Francisco businessman, for multiple sclerosis research and treatment at Stanford.

Previous speakers included Barry G.W. Arnason (1977), Richard T. Johnson (1978), Guy M. McKhann (1979), and John R. Kurtzke (1980).

The 1981 Achievement Rewards for College Scientists (ARCS) Scholars from Stanford University School of Medicine are Gary S. Richardson and Martin E. Kernberg. Both students received ARCS scholarships at a luncheon given in San Francisco, on March 5.

Affiliated with the Sleep Disorders Center, under the direction of Dr. William C. Dement, Richardson has been involved with sleep research at Montefiore Hospital in New York City and at Stanford since 1975.

Kernberg, who works at the Palo Alto Medical Research Foundation, is involved in cardiovascular research. At Stanford, he has worked with Drs. Edwin Alderman, Neil Ingels and Margaret Billingham.

The ARCS Foundation is a non-profit organization, founded in 1958 and based in Los Angeles. Its purpose is to provide funds for outstanding students of exceptional achievement and promise, involved in doctoral programs in physical science, life science or engineering.

STANFORD—

Dr. Hugh O. McDevitt, the Joseph D. Grant Professor in the School of Medicine, has been awarded the 1981 Passano Foundation Award in recognition of his research on "the relationship between the immune system, histocompatability antigens and human disease."

He will receive the award along with an honorarium of $25,000 in Baltimore, on March 31.

McDevitt, 50, has been a pioneer in uncovering the relationship between the genetic control of the body's immune response and the body's susceptibility or resistance to various diseases.

He discovered that genes in the mouse called immune response genes, which control the mouse's ability to respond to infection, are clustered together on one chromosome, and that they are closely linked to genes responsible for recognizing histocompatability antigens and thus destroying transplanted tissue grafts. Analogous immune response genes are present in man also and appear to be associated with susceptibility or resistance to diseases such as ragweed hayfever, several autoimmune diseases and arthritis, multiple sclerosis, psoriasis, and cancers such as acute lymphocytic leukemia in children and Hodgkin's disease.

McDevitt received a bachelor's degree with honors from Stanford in 1952 and an M.D. degree from Harvard Medical School in 1955. Before coming to Stanford in 1966, he taught bacteriology and immunology at Harvard.

Among his other honors are election to the National Academy of Sciences and the 1977 Borden Award for outstanding research from the Association of American Medical Colleges.

Beginning in 1945, the Passano Foundation, a Baltimore-based nonprofit corporation existing solely to encourage medical research, has each year presented an award to a person or persons who have made an outstanding contribution to the advancement of medical science and whose work was done in the United States. The Directors give prime consideration to work that has immediate clinical value, or that shows promise of practical application in the near future.

Founded by the late Edward Boteler Passano, then Chairman of the Board of the medical and scientific publisher The William and Wilkins Co., the Foundation has honored 43 scientists. Of these, nine have subsequently won a Nobel Prize for their work.

STANFORD—

The brain is the body's grand communicator; its stock in trade is sending and receiving messages. Billions and billions of nerve cells are abuzz with signals, communicating with one another and with other parts of the body.

Two Stanford University School of Medicine researchers have found that in the brain's highest centers there may be more than one way to get the message across. The way they've discovered is speedier than the most common way of sending and receiving messages in the brain, and so it may be important in epilepsy, a disorder characterized by large numbers of nerve cells firing at the same time.

Michael J. Gutnick and David A. Prince of the department of neurology report in a recent issue of *Science* magazine that electrical connections apparently exist between the nerve cells in the cerebral cortex, an area of the brain important for learning, memory, perception, and consciousness.

The most common way for cells to propagate their messages in the cerebral cortex is through the use of charged chemicals called neurotransmitters. A nerve can be thought of as a one-way live wire: if a cell is turned on at its one end, an electrical signal rushes to the other, causing little packets of neurotransmitters to be dumped out. The neurotransmitters zip to other cells, giving them the signal to either turn on or turn off.

What Prince and Gutnick found is that while the signal is rushing down the nerve cells, if parts of other nerve cells are joined in just the right way, through so called "gap junctions," then the signal can jump from one cell to another, much like a spark jumps between two live wires.

This is important because messages can spread much faster if they're going through the electrical connection route than if they're travelling part way through neurotransmitters. If the message can travel so fast, then many cells can be turned on to fire at the same time. Since many nerve cells firing at the same time is a distinguishing mark in epilepsy, Prince hypothesizes that such electrical couplings may play an important role in the disorder.

Prince and Gutnick did not discover this type of nerve conduction; it's been known for some time. Until now, however, electrical couplings have only been reported in the "more primitive" or lower parts of the mammalian brain, not in the higher brain centers. The conventional wisdom has been that electrical coupling of cells is a property of primitive nervous systems, such as those of the electric eel, Prince says.

Prince speculates that these electrical couplings may be more important than previously thought, however, in normal as well as in abnormal brain function. He and Gutnick found that the cells that were electrically coupled were sometimes in columns. It's been known for some time that columns of cells in the higher brain regions act as units in receiving, processing and sending information. Prince says electrical couplings may make it possible for these cells to act as a unit by spreading the message so quickly among them.

Prince plans next to investigate whether electrical coupling between nerve cells plays an important role in the development of epilepsy after brain injury. He will continue using animals for his studies; this initial work was done in guinea pig brains. But, he hopes that such experiments on electrical coupling will eventually lead to a better understanding of the development of epilepsy in the human brain.

CITY EDITORS: A press conference with Drs. Reitz and Shumway is scheduled for noon, Monday, March 9 in room W001 at Stanford University Hospital, 300 Pasteur Drive in Palo Alto.

STANFORD—

The first combined heart and lung transplant in humans in almost 10 years, the fourth one ever done, was performed at Stanford University Medical Center on March 9 by a team of surgeons led by Dr. Bruce A. Reitz and Dr. Norman E. Shumway.

The patient, Mary D. Gohlke, of Mesa, Arizona, is reported in stable but critical condition in the Hospital's intensive care unit following the four-hour operation. She received the heart and lungs of an anonymous donor whose body was flown from southern California.

"So far the patient looks very good," said Reitz. "The heart is functioning normally and she is breathing with the help of a respirator."

He added that the critical period will come in 24 hours when an attempt will be made to wean the patient from the respirator.

The operation began at 12:30 a.m. and was completed at 4:30 a.m.. In addition to Reitz and Shumway, other physician members of the team included Drs. John Pennock, Edward Stinson and John Wallwork. Nurses involved in the transplant included Aggie Boyles, Peggy Hartin, Jackye McGraw, Grace Neal, Margaret Paskert, Jan Vorwerk, and Sue Young.

Gohlke, 45, is advertising director with the Mesa Tribune (a Cox chain newspaper) of Mesa, Arizona. She is the only woman executive on the advertising side on any Cox newspaper, and she rose to her position in three years.

Her husband, Karl, is an engineer and they have two sons, Lucas, 14, and Christopher, 17.

Gohlke has been suffering from pulmonary hypertension. After she became ill with a cold in November, 1979, she thought she was coming down with her usual bronchitis, but it was diagnosed as pneumonia. In February 1980, her conditon was diagnosed as primary pulmonary hypertension and by March of that year, she was only able to work four hours a day.

She was forced to take disability leave from her position, but hopes to return to work after recovering from the operation.

Gohlke came to the Stanford area with her mother, Bea Martin, several weeks ago in order to be close to the Hospital.

On her decision to have the operation, Gohlke recently commented, "we would still be in the trees eating bananas if we didn't try things. We've got to try, not just sit on our hands. If I die, I want to leave my family, my sons the thought that at least Mom tried."

-more-

Her mother said, "she's gutsy, she's always been gutsy."

The 1972 discovery of the drug cyclosporin A set the stage for this new attempt to successfully replace at the same time both heart and lungs. Cyclosporin A circumvents two previously formidable obstacles in heart-lung transplants: the slow and imperfect healing of the windpipe and life-threatening infections.

Dr. Bruce A. Reitz, assistant professor of cardiovascular surgery at Stanford Medical School and head of the transplant team, estimates that the Stanford team may do three to four of these operations each year, considerably fewer than the 20 heart transplants it did last year. Not only do fewer people need a combined heart-lung transplant, but suitable donors are also harder to find, Reitz says.

As is true with heart transplant candidates, only persons judged to be dying and unable to be helped by any less drastic treatment will be considered for the operation.

For some patients with heart disease, replacing only the heart is not good enough. Their lungs have been irreparably damaged due to the high blood pressure resulting from a poorly-pumping heart. Patients with damaged lungs, resulting from either a failing heart or widespread disease in the lungs themselves, are a poor risk for a heart transplant. The damaged lungs resist the "new" heart's efforts to pump blood into them, straining the heart. The only recourse is to replace both the heart and the lungs.

Likewise, some patients who initially have just lung disease, such as pulmonary hypertension, or pulmonary or cystic fibrosis, end up with a damaged heart that needs to be replaced as well.

Although the success rate for heart transplants has improved in recent years (70 percent of the transplant patients now survive the first year), the replacement of lungs has met with failure. According to Reitz, in the 38 attempts up to 1977, only two patients lived longer than three months after surgery, and none survived longer than ten months.

The three previous combined heart-lung transplants, performed between 1968 and 1971, fared even worse: the patients survived only 14 hours, and 8 and 23 days.

One of the reasons success is yet to come in transplanting lungs is that the windpipe, or trachael tube, fails to heal completely, resulting in infection, air leakage or bleeding. The windpipe is slow and difficult to mend for a number of reasons, a major one being its scanty blood supply, which hinders healing.

Corticosteroids, until now the standard drugs given to prevent the body from rejecting the "foreign" lungs and an essential ingredient in the high success rate of heart transplants in recent years, slow down and antagonize the healing process even more. Cyclosporin A is such a find because it enables the surgeons to replace or decrease the dose of coricosteroids, and doesn't itself interfere with the windpipe's healing.

Cyclosporin A, a metabolite of the fungus Trichoderma polysporum, is composed of 11 amino acids hooked together to form a ring. It was discovered by Sandoz Pharmaceuticals of Basel, Switzerland. Sandoz has made the drug available for clinical trials to transplant surgeons in Britain, France, Canada and the United States during the last three years, and it has been used in kidney, liver, pancreas and heart transplants.

Exactly how cyclosporin A works is unknown, but it appears to inhibit the action of those cells of the body's defense system responsible for rejecting foreign tissue, the so-called T cells.

Reitz and Drs. Nelson A. Burton and John L. Pennock lay the groundwork for the operation working with monkeys. In tests during the past several years, they reinvestigated the possibility of heart-lung transplants with their new drug in hand. Results were encouraging. Three of seven monkeys receiving "new" hearts and lungs and being treated with cyclosporin A survived more than 140 days after surgery. Two are still living, 14 and 15 months after the operation.

Reitz says a major problem will be finding suitable donors. Donors will have to have both normal heart and lungs, and must be compatible with the blood type of the recipient.

Reitz anticipates that some donor lungs will be disqualified because they are infected.

Infection is the bugbear of transplant patients. The drug therapy, which suppresses the body's immune system, thus preventing rejection of the transplanted organ, also permits infections to gain a toehold. Infection has caused a third of all deaths in heart transplant patients, and the most common site has been the cells of the lungs. Another critical advantage of cyclosporin A is that it doesn't interfere with the immune system responsible for battling bacteria, while it inhibits those responsible for rejecting transplanted organs.

The choice of donors will be limited to those near Stanford Medical Center, because a method hasn't been worked out by which a heart and lung combination can be transported for any distance outside the donor's body, Reitz says. Since 1977 the number of potential donors for heart transplants has been greatly increased by a method to protect the heart in sterile bags and place it on ice after removing it from the donor and flushing it with a cold salt solution. Cooled hearts have been flown to Stanford in a chartered jet from up to 450 miles away.

Although, conceptually, replacing both the heart and the lungs (essentially the entire contents of the thoracic cavity) seems a mighty job, its actual execution is elegant, involving relatively few cuts and reconnections, once the overlying membranes are cut away.

Four surgeons work an average of four hours. Tubes are inserted into a major artery and two major veins just before they enter the heart so that the patient can be put on a heart-lung machine that will keep the blood flowing to all the other parts of the body. After the blood has been successfully detoured through the heart-lung machine with the help of clamps downstream on the artery and vein, the heart and lungs are removed with only three cuts; the ascending aorta (the major artery), right upper chamber of the heart and the windpipe, or trachae, are severed. The new heart and lungs are then put in, the three areas reconnected, and the blood diverted back through the new heart.

If the operation seems relatively simple, the balancing act performed after the operation does not. The body's immune system must be suppressed enough that it cannot mount an offensive against the new thoracic tenants, but yet not so suppressed that it cannot fight off the least infection.

-more-

The new organs must be monitored regularly to see if they are under seige, and if they are, the dose of immunosuppressive drugs increased to avert a rejection.

A technique was developed several years ago to sample directly a small piece of the heart for early signs of rejection that can't be detected by more conventional methods. A thin, flexible wire with a clipper at the end is inserted in the patient's jugular vein and threaded down into the transplanted heart to obtain a small sample of tissue. This ability to directly assess the heart transplant accounts for a goodly part of the increased success rate in recent years.

This technique has not proved useful for lung transplants, Reitz says, and so it is hard to detect the first signs of rejection when only lungs are transplanted. In the combined heart and lung transplants, evidence of rejection of the heart means also rejection of the lungs, and therapy can be begun before the situation is out of control.

Although cyclosporin A is the best drug yet found for heart-lung transplants, it is not without its undesirable side effects. Most serious is the potential development of malignant lymphoma, a form of cancer that has been previously associated with immunosuppression. Three kidney transplant patients in recent clinical trials of cyclosporin A conducted at Cambridge University in England developed lymphomas in the first year. The research team in England has since lowered its dosage of cyclosporin and no new lymphomas have been detected.

Other side effects of the drug include mild cases of hair growth on the face and limbs, tremors, and toxicity to the kidney.

Cyclosporin A is still an experimental drug on which all the evidence is not in. Yet no drug now available to a transplant patient, who must take drugs the rest of his life, are without undesirable side effects. Cyclosporin A may give a patient with failing heart and lungs, who otherwise faces a sure and near death, the possibility of a successful transplant, Reitz says.

STANFORD—

A Stanford University student was raped in a Stanford Medical School laboratory during the first week of February around midnight.

Marvin Herrington, director of the Stanford Public Safety Department, is releasing a description of the rapist in order to alert the community to be aware of any suspicious persons.

The rapist is described as a white male in his early to mid 20's, of medium height and build, with dark brown collar length hair. At the time the attack took place, he was wearing a green hospital scrub suit and a T-shirt.

According to Herrington, the rapist approached by entering the laboratory where the student was studying, turning off the light, and then assaulted the victim, who subsequently required medical treatment.

The rape victim, who does not want to press charges and wishes to remain anonymous, did not report the rape to the Stanford Public Safety Department until February 24, according to Herrington.

Herrington stresses that anyone in the Medical Center who notices a suspicious person meeting this description should contact the Hospital's Department of Safety and Security immediately at extension 7-7222, or they may contact the nearest police department, either Stanford's Public Safety Department or the Palo Alto Police Department. Both departments are investigating the case, although the incident occurred in the Medical Center, which is under Palo Alto police jurisdiction.

There are as yet no suspects.

STANFORD—

Michael Cowan has been appointed director of Public Events at Stanford University Medical Center, and executive officer of the Medical Alumni Association, announced Lawrence G. Crowley, vice president for Medical Affairs.

Cowan, who succeeds Barbara Norton in these areas of responsibility, will be involved in vigorous program development for both. Public Events programs will include tours, a Progress in Medicine lecture series and a speakers' bureau.

"By next winter," says Cowan, "the program will be ready to reach actively into the community, rather than just respond to outside requests as they come in."

This month, the office is settling at 800 Welch Road.

Cowan has been assistant to the vice president for Medical Affairs and dean of the School of Medicine since April, 1978.

Prior to that, she served as financial aid administrator of the Medical School, and as a financial assistant in the University's Student Accounting Office.

She has been a consultant to the Department of Health, Education and Welfare, and to the Calfornia Student Aid Commission.

Cowan received her B.A. in rhetoric at U.C. Berkeley and did graduate work in speech at U.C.L.A. She also attended the Calfornia Graduate Institute of Psychoanalytic Psychology.

Cowan lives in Menlo Park with her son.

STANFORD—

A new but as yet little known applied science called genetic toxicology may soon become as widespread as general toxicology within the chemical and drug industries, predicts a Stanford University Medical School professor.

Toxicology testing of new substances to determine their harmful effects on the body is one of business's responses to the public demand for more assurance of safety concerning new products. Genetic toxicology goes beyond general toxicology to study the specific effects of chemicals on the genetic material (DNA), explains Dr. Errol Friedberg, associate professor of pathology.

DNA can be damaged by a wide variety of chemicals and by certain wavelengths of radiation—if not repaired, the damage may lead to permanent mutations, or to diseases, including cancer.

In fact, it is believed that one significant cause of cancer may be abnormal repair or lack of repair of damaged DNA, according to Friedberg.

Many industries are already setting up laboratories for genetic toxicology programs, hiring scientists whose specific job will be to determine the degree to which products under consideration for manufacture and marketing cause damage to DNA.

"It's an entirely new application of the techniques of DNA repair research," says Friedberg.

In theory, he adds, exquisitely sensitive tests could be developed to monitor DNA damage within the cells of individuals exposed to high risk chemicals or radiation.

In part, to meet the demands of this new technology, Friedberg and his colleague, Dr. Philip Hanawalt, professor of biology, have compiled a book that provides "cookbook" detail about current laboratory procedures in DNA repair research. The book, *Laboratory Procedures for Research in DNA Repair* has just been published by Marcel Dekker, Inc..

In the preface to the book, Friedberg and Hanawalt state that "after almost half a century of active research, the terms DNA damage and DNA repair have come to have much broader significance than might have been anticipated.

"It is now abundantly clear that the plethora of chemical agents that 'contaminate' our environment constitute a major (if not the major) source of biologically significant damage to the genetic material in living cells."

The vital information contained within the DNA of the human body would be reduced to gobbledegook if it were not for the sophisticated cellular repair systems that Friedberg and Hanawalt have been studying for many years.

-more-

2-2-2

In order to understand how DNA damage and repair occur, it's helpful to imagine the structure of the DNA molecule, Friedberg suggests.

DNA consists of extremely long chains of small molecules called nucleotides which are strung together in a precise sequence in which is encoded all the vital information for the cell's growth and survival, he explains. Triplets of bases form the "words" of the DNA language, and an alteration in one base can completely alter the sense of the "word".

Damage to DNA can take the form of a deleted base or stretch of bases, chemical alteration of bases, abnormal binding together of adjacent bases, or one or more breaks in the long DNA strand.

Various enzymes within cells recognize these specific types of damage and repair the mistakes, restoring the cell's original complement of genetic information, Friedberg explains. For instance, there is a specific enzyme that recognizes and repairs two adjacent pyrimidine bases that have bonded to form a nonfunctional pair, or "dimer". If left unrepaired, such dimers disrupt the normal uncoding system that processes the information contained in DNA

Normally, DNA repair enzymes maintain genetic order within our cells. But what happens if a component of the repair system itself is defective? Serious disease may be the result, says Friedberg.

For instance, he is studying an uncommon disease called xeroderma pigmentosum—patients with this hereditary condition have a 100 percent probability of developing skin cancers, a type of malignancy associated with ultraviolet radiation from the sun and other sources.

Individuals with the disease have a defect in the enzyme that repairs DNA damage caused by ultraviolet radiation.

Another of the 15 or more diseases now suspected to be caused by defective DNA repair systems is ataxia telangiectasia, which is associated with a high incidence of cancer of the lymphatic system, Friedberg notes. Radiotherapy or x-rays cause many such patients to become seriously ill, because of a defect in the repair of x-ray damage to DNA.

Despite increasing evidence that environmental chemicals are a major source of damage to DNA, the relationship between environmental "contamination" and human cancer is still very controversial, says Friedberg.

But it is important to closely monitor new chemicals to establish their genetic toxicity, particularly to ensure safe exposure levels for industrial workers who experience prolonged contact with the materials, he maintains.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

Dr. Ferid Murad, professor of medicine and pharmacology, and director of the Clinical Research Center at the University of Virginia Medical School, will present the Pfizer Lecture on Friday, March 13, at Stanford University School of Medicine.

The public lecture begins at 3:15 in room R-358.

Murad's main research areas are cell biology and molecular pharmacology. He has been a leader in trying to understand how the compounds cyclic GMP and AMP regulate a whole series of cellular functions.

He is especially interested in discovering where the enzyme guanylate cyclase—which produces these compounds—is located in the cell, and what regulates its activity.

In his lecture, entitled "Guanylate Cyclase: Purification, Characterization and Preparation of Monoclonal Antibodies," Murad will discuss his use of monoclonal antibodies in characterizing the enzyme.

The Pfizer Lectures are sponsored by the Division of Clinical Pharmacology and the Department of Pharmacology at Stanford Medical School. They are funded by Pfizer Pharmaceuticals, Pfizer Inc. of New York City.

STANFORD—

Did you know that Stanford University Hospital's pharmacy fills an average of 1,283 prescriptions a day?

Or that the Auxiliary's contributions to the Hospital since 1959 include more than 1,450,000 service hours and $659,000?

Or that in 1979-80, the School of Medicine received gifts of $16,426,000?

These are just a few of the many facts spelled out in the Stanford University Medical Center *Facts* booklet of 1981. Take this one: tuition per quarter, for the School of Medicine, was $50 in 1920; in 1981 it's $2,780.

For copies of *Facts*, write to: Publications, Office of Medical Development, 780 Welch Road, Suite 106, Palo Alto, California 94304; or call (415) 497-5036.

STANFORD—

The Stanford University School of Medicine which, according to earlier forecasts would have faced a budget deficit of up to $2 million in fiscal 1980, has ended the year in the black, Dr. Lawrence G. Crowley, vice president for medical affairs and acting dean, told the School's Faculty Senate last week.

"We assess the financial health of the Medical School to be sound," Crowley said, adding that he expects balanced budgets for the next two years if present assumptions for inflation, salary increases, energy costs and other factors hold true.

Crowley said the anticipated deficits forecast in 1978 and 1979 were avoided by holding down the expenses in the School's operating budget, postponing capital improvements, new income and improvements in research support.

However, the present optimistic outlook does not mean there are no problems, he said. "While we have attempted to address our capital needs in a rational manner, there is still a gap between those projects we would like to do and those which we can afford.

"Utility costs are escalating at an alarming rate. It still remains difficult to accurately predict faculty activity in the clinical and research areas. The School is highly dependent on indirect cost recovery from sponsored research, and faculty practice income for both operating and capital needs.

"Thus, we must constantly monitor our income and expenses to maintain our present good health."

Clouding the fiscal horizon further, Crowley added, is the uncertainty of future research funding under the new administration in Washington and policies which have yet to be developed.

"Prudence dictates, therefore, that we be conservative, and attempt to consolidate our position based on the fact that Stanford has done well in a declining research market due to the quality of its faculty and, hence, strong competitive position," he said.

The financial long-range forecast report prepared by David Mendelow, associate dean of the School of Medicine, was developed this year on a mathematically structured computer simulation model. The purpose is to set formal constraints on the next year's budget development and to establish financial direction for a number of years ahead.

"We approach this year's forecast with increased maturity, sophistication, and understanding of our financial environment," Mendelow wrote.

The School's current operating budget, excluding sponsored research, is $20.8 million. Academic department expenses comprise 56 percent of the total expense. Faculty and other teaching salaries are 31 percent of the total and 55 percent of the academic departmental expenses. Utilities are the second largest item, 13 percent. Administration, and operations and maintenance are each 12 percent. Academic support, including library expenses, are 7 percent of the total.

These assumptions were used in preparing the long-range forecast, according to Mendelow:

- inflation is projected at 10.5 percent for fiscal 1980 and 1981, decreasing to 10 percent in each of the next two years.

-more-

• faculty salaries are expected to rise 2.5 percent above inflation in 1981, and one percent above inflation in the next two years. Staff salaries are also expected to increase "to correct current seriously non-competitive situations."

• energy costs, based on calculations of Medical School uses of energy, are expected to rise 17.5 percent, 11.6 percent, and 23.5 percent in the next three years.

The financial forecast, in addition, assumes a modest faculty growth in selected basic science and clinical departments reflecting programmatic needs, and modest increases in sponsored research, and in clinic visits.

The class size, according to the report, will remain the same. Tuition increases, forecast by University budget assumptions, will be at 3.1 percent above inflation for fiscal 1981, and two percent in subsequent years. Federal capitation grants, originally provided to encourage schools to train more physicians, will be phased out in 1981.

The combined effects of unrestricted income loss and essential new programs have resulted in an increase in the budget of academic support services, Mendelow said.

He noted, for example, that restricted funds for library acquisitions are not keeping pace with rising costs. Hence, more and more of the library's acquisitions must be covered by the School's operating budget.

A new element added this year to the School's long-range forecast concerns capital improvements. "Our outlook has broadened," he said, "for we recognize that capital investment is an integral part of any long-range financial plan."

Postponement of much needed capital improvements has resulted in plant and program deterioration in so many areas, and this must be corrected. Mendelow said a number of major capital initiatives are contemplated in the future.

"The source of funds include major gifts, federal grants, and School reserves," he said. "However, it is clear to us that a major gap exists in our ability to meet our major project needs."

He said that while the School has increased its reserves to the extent that it is able and is now studying how much, if any, can be used for capital improvements, a comprehensive plan will have to evolve on how these projects should be funded.

STANFORD—

The Stanford Alcohol Clinic will sponsor a series of four public lectures in March and April designed to increase understanding of problems and issues surrounding alcohol use and abuse.

The meetings will take place on four successive Monday evenings starting March 16 at 8 p.m.. They will be held in Room M112 of the Stanford Medical School, located on the inner courtyard at the south corner of the Medical School.

The programs will address concerns of individuals and families and will cover treatment possibilities and results of recent research on alcoholism.

According to Dr. Emily Garfield, educational coordinator for the Alcohol Clinic, this series was arranged in response to public interest on the part of those concerned about alcohol—their own drinking, someone else's, or issues in sobriety.

Dr. Stephanie Brown, clinical psychologist and director of the Clinic, will open the series March 16 with a talk entitled "What is Too Much Alcohol?". Brown is recognized for her innovative work on the causes and treatment of alcoholism, and on children of alcoholics.

Subsequent programs, all to be held at 8 p.m. and conducted by members of the Alcohol Clinic staff, include:

March 23—"Alcohol and the Family," with Dr. Susan Beletsis, clinical psychologist and therapist;

March 30—"Children of Alcoholics," by Dr. Tim Cermak, psychiatrist;

April 6—"Alcohol as it affects Adolescents, the Elderly, and Other Groups," with Dr. Emily Garfield, Clinic educational coordinator.

STANFORD—

"Her prognosis seems better now than at any time in the past three weeks."

These were the words of Dr. Bruce Reitz, speaking of the recovery progress of 45-year-old Mary D. Gohlke of Mesa, Arizona.

Mrs. Gohlke, advertising director with the *Mesa Tribune*, received a combined heart-lung transplant at Stanford University Hospital March 9. It was the first such transplant in humans in almost 10 years, and the fourth one ever done, according to Reitz and Dr. Norman Shumway who performed the four-hour operation.

The operation was the culmination of more than two years of experimental work in primates, conducted by Reitz and his associates in the Stanford cardiovascular laboratory.

In his first major statement since the operation, made in response to numerous press queries, Reitz emphasized that Mrs. Gohlke still faces a long road to recovery. "And unforeseen problems could arise."

But he added, "The mild rejection of her new heart and lungs that beset her at 10 days after surgery has now been completely reversed, and by every indication, her windpipe is healing adequately."

The healing of the windpipe has been a particularly troublesome problem in past heart-lung transplants, Reitz explained.

"We are especially encouraged that it has thus far posed no problem for Mrs. Gohlke."

Reitz said that now the major potential risk that could hamper Mrs. Gohlke's recovery is infection.

"She has suffered no infections to date," he said.

This is an encouraging sign, according to Reitz, but she will be watched closely for signs of infection in the next few months.

Reitz did not rule out further rejection episodes which are not unexpected in transplant patients. "If another episode should occur, we expect that we will be able to catch it early on and control it," he said.

According to Reitz, the smooth healing of the windpipe and the absence of infections thus far is due to the specific action of the drug Cyclosporin A as compared with other immunosuppressants previously available.

"Mrs. Gohlke," said Reitz, "now faces the challenge of rebuilding her strength and stamina. In the last few days she has shown steady improvement."

He explained that Mrs. Gohlke has begun physical therapy, such as lifting very light weights, and is even being taken outdoors for a change of scenery.

Although she is still very tired, she is beginning to regain her pre-operation sense of humor. "How are the monkeys?" she asked Reitz recently, referring to the animals used to make this experimental work possible.

Reitz said Mrs. Gohlke is expected to remain in the hospital at least another month and a half. "We hope she will be able to move from the intensive care ward to a general one in perhaps two to three weeks.

"Throughout, Mrs. Gohlke has shown great spirit and determination and she appreciates the encouragement she has received from many people," Reitz said.

He also stressed the experimental nature of the operation. "We are learning, and happily, all the lessons thus far have been good."

CITY EDITORS: A press conference with Willie and members of the Pediatrics staff is scheduled for 9:30 A.M., Friday, April 3, in the Pediatrics playroom at Stanford University Hospital, 300 Pasteur Drive in Palo Alto. STANFORD—

Eleven-year-old William Ramirez may get to go home soon.

When that happens, he'll be the first ventilator-dependent, quadraplegic child, receiving financial support from state agencies, ever to go home from a hospital in the tri-county region of Alameda, Santa Clara and San Mateo.

"We've been hoping to set a precedent with Willie," says clinical social worker in Pediatrics Maria Nasjleti who, along with many other dedicated staff members, has been planning Willie's return home for many months.

In the past, social agencies such as MediCal and the California Children's Service have provided financial support for children like Willie while hospitalized, but not at home. Willie's parents, both of whom work full time, moved with their four children to the U.S. from Mexico four years ago. They cannot afford, on their very limited income, the medical equipment and renovations that would be required to bring their son home.

Willie was initially hospitalized at Stanford University Hospital on December 15, 1979, after being hit by an automobile driven by an uninsured motorist in his hometown of Hayward, California. He was paralyzed from the neck down.

In May, 1980, Willie was transferred to the Santa Clara Valley Medical Center for rehabilitation services. While there he learned to type on an electric typewriter with a mouth stick, paint and talk again. He returned to Stanford last August.

After a very complex struggle requiring the participation of Hospital staff members with varying skills and responsibilities, the state has agreed to pay for Willie's medical equipment at home, transportation for medical check-ups, and all medical supplies including medications. It will also pay nurses' fees for trial home visits, prescribed by Dr. James Loomis, Willie's attending pediatrician. (The three visits he has had so far, reports Nasjleti, went exceedingly well.)

Staff involved in the group effort include physical therapists, occupational therapists, respiratory therapists, recreation therapists, neurosurgeons, pediatricians, psychiatrists, Willie's primary nurses, the clinical nursing coordinators (C.N.C.'s) and the pediatric resident staff.

"But with all of our work," says Dorothy Holmes, assistant C.N.C., "we couldn't have gotten anywhere without Willie's outstanding adjustment and spirit, unusual for a child his age. And his mother is a pretty amazing woman, too," she adds.

-more-

"The state's willingness to set this precedent," says Nasjleti, "demonstrates that in the future it will be possible for other children like Willie to go home instead of having to be institutionalized." Without the assistance that's been granted, she explains, Willie would need to live in an institution for the remainder of his childhood years. And, she adds, there appear to be very few community resources designed for handicapped children, the services that *do* exist accommodating only those 16 or over.

"I think this is because kids require more than adults do, in terms of supervision of daily activities," says Holmes. But, she adds, as more and more severely injured children are surviving now, provisions need to be made for training families and setting up households.

But Willie does have a special card which enables him to ride the Sam Trans Redi-Wheels buses, specifically built for handicapped and disabled persons.

And he's been attending the Loma Vista school in Palo Alto regularly, while the Hospital is still his home. "Establishing a school program for a needy child is difficult," says Nasjleti, "and the district has done a wonderful job." Willie, she adds, is the first child on a respirator to be admitted into the Palo Alto school district.

"A charmer" is one way to describe Willie, says Nasjleti. His engaging personality and sense of humor may be part of the reason, she suggests, that he has enlisted the interest and support of so many staff members at Stanford.

"They have just hung in there for so long and shown such patience," says Nasjleti, explaining that Stanford, a center for acute care rather than rehabilitation, is not usually equipped to deal with such a long-term project.

"It would have been much easier to send Willie somewhere else once he was stable," she continues. "This has been a real humanitarian effort."

Says Holmes, "The only reason Willie has had to stay at Stanford for a year and a half is that there's no other institution in California that could take him. The rehabilitation facilities are just filled to the brim."

An exceptionally bright and talented child, Willie has been extraordinarily brave since his precipitous accident, often boosting the morale of those who care for him. "He has not shown bitterness about his accident," says Nasjleti, "though of course he has his moments." His attitude has been one of hope, courage and determination."

Holmes explains that Willie has adjusted well to his lifelong impairment, and is able to do a lot more now than he could at first. His phrenic nerve pacers allow him to be off the ventilator for five to six hours, on good days. "He's gotten more used to his situation, but he had to put lots of hard work into it," she says.

Speaking both English and Spanish, Willie has made a variety of friends during the course of his stay here. He and an accomplice recently wrote a three-page plan for taking over the Hospital!

But Willie's real claim to fame lies in his mastery of a particular computerized game. The company that produces it (and donates new materials to Stanford's playroom every year) recently asked if the Ramirez' would consent to Willie doing commercials! Sure enough, they have agreed.

-more-

3-3-3

Willie's parents made a commitment early on to do whatever is necessary for Willie to return home. Though they speak only Spanish and therefore require interpretors, they have been taught intensively by Stanford personnel to care for their son at home.

"I think it's his family's faith that's the bulk of their strength," says bilingual Nasjleti, adding that Willie's return home will mean a tremendous change in lifestyle for the entire family. The transition, she says, will be wrought with many social, psychological and emotional hurdles.

The only thing keeping Willie in the Hospital now, says Nasjleti, is the lack of a suitable house for his family. The Ramirez' present home is not large enough to accommodate all the modifications necessary for Willie's care. Among other items, electrical work would need to be done, a furnace installed, and several access ramps built.

Luckily, the Ramirez family has been approved to participate in a federally funded rent subsidy program, administered by the city of Hayward. They are searching for a new home, with the help of the Hayward Community Housing Advisory Service.

Willie has two older brothers and an eight-year-old sister. Because of certain program requirements, the house they find must have four bedrooms.

Meanwhile, says Nasjleti, the telephone company has devised a special, inexpensive speaker system for handicapped people. Willie will have one in his new home.

And both Pacific Gas and Electric and the Hayward fire department have agreed to provide "life-line services" to the family. This means that in case of emergency or machine malfunction, help will arrive at the Ramirez house momentarily.

Willie will probably attend the Sunset School for Orthopedically Handicapped Children in Hayward.

If he didn't go home to his real family, says Holmes, Willie might have to be placed in a foster home. The hope now is that things will work out for the Ramirez', once they find an appropriate house.

"Those of us who have worked with Willie look forward to the wonderful day when he can go home," says Nasjleti. "Still, after all this time, it will be sad in a way." It's apparent, though, that none of the parties intend to lose contact.

Any groups or individuals wishing to make donations for Willie's care should contact Alice Morrow, R.N., clinical nursing coordinator in the Pediatrics unit at Stanford University Hospital, 300 Pasteur Drive, Department of Nursing Services, Stanford, California 94305. Morrow's phone number is (415) 497-5351.

TWO STORIES: Lisa Ames (415) 497-6911

STANFORD—

A new group program called "Social Skills for Singles" will soon be offered by the Department of Psychiatry's Stress Reduction Clinic at Stanford. The series is similar to one conducted in 1980.

Designed for single adults who experience some discomfort with social interactions, the group will meet at the Clinic on Mondays at 6 p.m., for eight weeks, beginning May 11.

The major focus of the group will be to teach communication skills for initiating conversations, maintaining them, and requesting future meetings. These skills will be described, demonstrated, discussed and practiced. In addition, concerns during social interactions, as well as places and ways to meet people will be discussed.

Group leaders will be Barbara Newman, a licensed marriage, family, and child counselor, and Carl Viesti, Jr., a licensed psychologist.

Interested people will be interviewed, beginning April 20, to determine whether the group will benefit them. There is a small fee per session for those who enroll.

For further information or to schedule an interview, call Newman or Viesti at 497-6341.

—30— 213

STANFORD—

The next proud owner of a king-sized, handmade, Stanford album quilt will be selected on May 8, at the annual spring benefit of the Stanford Medical Faculty Women's Association.

Each year the Association, founded in 1961, raffles off the quilt (first prize), along with several other special items and gift certificates for hotels and restaurants. Funds raised go towards the Medical Student Scholarship Fund, started in 1967 by the Association under the presidency of Gladys Kirkman. Mrs. Kirkman has been leader of the quilting project, which attracts many participants, ever since.

Raffle tickets will be sold at Stanford University Hospital, April 20 through 24; at the Palo Alto Clinic April 27 through 29; at White Plaza April 30 through May 1; and again at the Hospital May 4 through 8. The quilt will be displayed at each sales location. Tickets cost $1.00 each, $5.00 for six, or $10.00 for twelve.

STANFORD—

Nisu mi sve koze na broju.

Do you know what that means? If so, you may consider volunteering as an interpreter at Stanford University Hospital.

The Hospital needs people who are fluent in different languages to act as interpreters for patients from many nations all over the world.

Although three professional Spanish interpreters, as well as many bi- and multi-lingual Hospital employees, provide translation services, they cannot provide all the assistance needed in a variety of languages, explains Jeanne Kennedy, director of Community Relations.

Kennedy is developing a "translator bank" of interested community members who would like to lend their linguistic expertise every so often. The number of times each individual would be called upon is probably small, she says, perhaps only once a year. But the effect on the patient's welfare would be enormous, she adds.

If you are interested, contact Kennedy at the Office of Community Relations, room P3018, Stanford University Hospital, or phone 497-7167.

Incidentally, the phrase in Serbo-Croatian means, literally, "I cannot account for all my goats," but any native speaker would understand it to mean "I don't feel myself today."

STANFORD—

If your mate helps you lose weight, you'll likely soon become slimmer and healthier, according to a new Stanford University study—even if your relationship is unhealthy.

Couples working together to help one overweight partner reduce achieved substantial weight losses with minimal assistance through a simple home study weight loss program, according to Stanford researchers. And, unexpectedly, the couples with the least successful relationships lost more weight working as partners than their more blissfully paired counterparts, the researchers report.

These are some of the surprising results from a year-long study of 23 couples enrolled in a home study weight loss program carried out through the Heart Disease Prevention Program at Stanford University School of Medicine.

The overall average weight lost by participants in the program was 23 ½ pounds, a heftier reduction than that obtained through many conventional weight loss behavioral techniques, reports William Threlfall, a doctoral student in counseling psychology and a member of the research team. Threlfall's colleagues on the project are Dr. Randy Black, formerly a postdoctoral scholar at Stanford University School of Medicine and now on the faculty at University of Nebraska Medical Center, and Judy K. Black.

The researchers note that there was no significant performance difference for males and females, although the program was by no means successful for everyone. One participant actually gained eight-and-a-half pounds although three-fourths of the participants lost at least 17½ pounds of their excess body weight, and one-third of the participants lost at least 33 pounds. "Altogether we were very pleased with the weight losses and long-term maintenance," say Black and Threlfall.

But "counterintuitively", they add, the unhappy couples managed a significantly greater weight loss—an average reduction of 32 pounds for the reducing member—when compared to the happier pairs, whose reducing members lost an average 19 pounds during the year.

The researchers explain that prior to the study they expected that people who could work together well would show greater losses. The researchers speculate that one of several possible factors contributing to the unexpected finding may be that motivation to improve personal appearance was higher among individuals struggling in, or considering leaving, an unsuccessful relationship.

(Happiness and unhappiness were determined by scores on several standard psychological tests, the researchers note.)

On the average, participants lost more than 38 percent of the total amount necessary for them to reach their ideal weight (calculated by a stringent formula often used in weight loss research). However, weight loss is not the only useful measure when evaluating obesity, the researchers observe. More impressive were participants' achievements in lowering their body fat content: on average, they lost more than 45 percent of the total amount necessary to reach an optimal level of body fat, and 17 percent of the participants actually achieved their ideal level of body fat, the research team reports. (The ideal for men is 14 percent body fat, and for women 24 percent.)

Two other observations intrigued the research team.

-more-

"Many of the overweight helping partners lost weight too, amounting to an average loss of nearly ten pounds," they note. In addition, many of those who successfully shed pounds also freed themselves of a high-blood pressure problem, a substantial health benefit believed to be associated with weight loss. "Of the 14 subjects who were initially hypertensive, only three remained so by the end of the year," the researchers explain.

The home reducing program was divided into three phases. During the first phase, which lasted 13 weeks on the average, couples engaged in some simple record-keeping concerning calories and body weight. The only contact the couples maintained with the research team amounted to mailing these records to a counselor on a weekly basis. The greatest reduction occurred during this treatment phase: subjects lost an average 14½ pounds and continued losing for an average of 13 weeks. "Three subjects required no further intervention to reach ideal body fat," the researchers report.

"We were surprised to see such substantial and extended weight loss during this time with so little involvement on our part," they note.
